Tornado is a Python web framework and asynchronous networking library, originally developed at FriendFeed. By using non-blocking network I/O, Tornado can scale to tens of thousands of open connections, making it ideal for long polling, WebSockets, and other applications that require a long-lived connection to each user.
CHAPTER ONE

QUICK LINKS

- Current version: 6.4.dev1 (download from PyPI, release notes)
- Source (GitHub)
- Mailing lists: discussion and announcements
- Stack Overflow
- Wiki
Here is a simple “Hello, world” example web app for Tornado:

```python
import asyncio
import tornado

class MainHandler(tornado.web.RequestHandler):
    def get(self):
        self.write("Hello, world")

def make_app():
    return tornado.web.Application(["/", MainHandler],)

async def main():
    app = make_app()
    app.listen(8888)
    await asyncio.Event().wait()

if __name__ == "__main__":
    asyncio.run(main())
```

This example does not use any of Tornado’s asynchronous features; for that see this simple chat room.
Tornado is different from most Python web frameworks. It is not based on WSGI, and it is typically run with only one thread per process. See the *User’s guide* for more on Tornado’s approach to asynchronous programming.

While some support of WSGI is available in the `tornado.wsgi` module, it is not a focus of development and most applications should be written to use Tornado’s own interfaces (such as `tornado.web`) directly instead of using WSGI.

In general, Tornado code is not thread-safe. The only method in Tornado that is safe to call from other threads is `IOLoop.add_callback`. You can also use `IOLoop.run_in_executor` to asynchronously run a blocking function on another thread, but note that the function passed to `run_in_executor` should avoid referencing any Tornado objects. `run_in_executor` is the recommended way to interact with blocking code.
Tornado is integrated with the standard library `asyncio` module and shares the same event loop (by default since Tornado 5.0). In general, libraries designed for use with `asyncio` can be mixed freely with Tornado.
pip install tornado

Tornado is listed in PyPI and can be installed with pip. Note that the source distribution includes demo applications that are not present when Tornado is installed in this way, so you may wish to download a copy of the source tarball or clone the git repository as well.

Prerequisites: Tornado 6.3 requires Python 3.8 or newer. The following optional packages may be useful:

- `pycurl` is used by the optional `tornado.curl_httpclient`. Libcurl version 7.22 or higher is required.
- `pycares` is an alternative non-blocking DNS resolver that can be used when threads are not appropriate.

Platforms: Tornado is designed for Unix-like platforms, with best performance and scalability on systems supporting `epoll` (Linux), `kqueue` (BSD/macOS), or `/dev/poll` (Solaris).

Tornado will also run on Windows, although this configuration is not officially supported or recommended for production use. Some features are missing on Windows (including multi-process mode) and scalability is limited (Even though Tornado is built on asyncio, which supports Windows, Tornado does not use the APIs that are necessary for scalable networking on Windows).
This documentation is also available in PDF and Epub formats.

6.1 User’s guide

6.1.1 Introduction

Tornado is a Python web framework and asynchronous networking library, originally developed at FriendFeed. By using non-blocking network I/O, Tornado can scale to tens of thousands of open connections, making it ideal for long polling, WebSockets, and other applications that require a long-lived connection to each user.

Tornado can be roughly divided into three major components:

- A web framework (including RequestHandler which is subclassed to create web applications, and various supporting classes).
- Client- and server-side implementations of HTTP (HTTPServer and AsyncHTTPClient).
- An asynchronous networking library including the classes IOLoop and IOStream, which serve as the building blocks for the HTTP components and can also be used to implement other protocols.

The Tornado web framework and HTTP server together offer a full-stack alternative to WSGI. While it is possible to use the Tornado HTTP server as a container for other WSGI frameworks (WSGIContainer), this combination has limitations and to take full advantage of Tornado you will need to use Tornado’s web framework and HTTP server together.

6.1.2 Asynchronous and non-Blocking I/O

Real-time web features require a long-lived mostly-idle connection per user. In a traditional synchronous web server, this implies devoting one thread to each user, which can be very expensive.

To minimize the cost of concurrent connections, Tornado uses a single-threaded event loop. This means that all application code should aim to be asynchronous and non-blocking because only one operation can be active at a time.

The terms asynchronous and non-blocking are closely related and are often used interchangeably, but they are not quite the same thing.
Blocking

A function **blocks** when it waits for something to happen before returning. A function may block for many reasons: network I/O, disk I/O, mutexes, etc. In fact, *every* function blocks, at least a little bit, while it is running and using the CPU (for an extreme example that demonstrates why CPU blocking must be taken as seriously as other kinds of blocking, consider password hashing functions like `bcrypt`, which by design use hundreds of milliseconds of CPU time, far more than a typical network or disk access).

A function can be blocking in some respects and non-blocking in others. In the context of Tornado we generally talk about blocking in the context of network I/O, although all kinds of blocking are to be minimized.

Asynchronous

An **asynchronous** function returns before it is finished, and generally causes some work to happen in the background before triggering some future action in the application (as opposed to normal **synchronous** functions, which do everything they are going to do before returning). There are many styles of asynchronous interfaces:

- Callback argument
- Return a placeholder (**Future**, **Promise**, **Deferred**)
- Deliver to a queue
- Callback registry (e.g. POSIX signals)

Regardless of which type of interface is used, asynchronous functions **by definition** interact differently with their callers; there is no free way to make a synchronous function asynchronous in a way that is transparent to its callers (systems like `gevent` use lightweight threads to offer performance comparable to asynchronous systems, but they do not actually make things asynchronous).

Asynchronous operations in Tornado generally return placeholder objects (**Futures**), with the exception of some low-level components like the `IOLoop` that use callbacks. **Futures** are usually transformed into their result with the `await` or `yield` keywords.

Examples

Here is a sample synchronous function:

```python
from tornado.httpclient import HTTPClient

def synchronous_fetch(url):
    http_client = HTTPClient()
    response = http_client.fetch(url)
    return response.body
```

And here is the same function rewritten asynchronously as a native coroutine:

```python
from tornado.httpclient import AsyncHTTPClient

async def asynchronous_fetch(url):
    http_client = AsyncHTTPClient()
    response = await http_client.fetch(url)
    return response.body
```

Or for compatibility with older versions of Python, using the `tornado.gen` module:
from tornado.httpclient import AsyncHTTPClient
from tornado import gen

@gen.coroutine
def async_fetch_gen(url):
    http_client = AsyncHTTPClient()
    response = yield http_client.fetch(url)
    raise gen.Return(response.body)

Coroutines are a little magical, but what they do internally is something like this:

from tornado.concurrent import Future

def async_fetch_manual(url):
    http_client = AsyncHTTPClient()
    my_future = Future()
    fetch_future = http_client.fetch(url)
    def on_fetch(f):
        my_future.set_result(f.result().body)
    fetch_future.add_done_callback(on_fetch)
    return my_future

Notice that the coroutine returns its Future before the fetch is done. This is what makes coroutines asynchronous.

Anything you can do with coroutines you can also do by passing callback objects around, but coroutines provide an important simplification by letting you organize your code in the same way you would if it were synchronous. This is especially important for error handling, since try/except blocks work as you would expect in coroutines while this is difficult to achieve with callbacks. Coroutines will be discussed in depth in the next section of this guide.

6.1.3 Coroutines

Coroutines are the recommended way to write asynchronous code in Tornado. Coroutines use the Python await keyword to suspend and resume execution instead of a chain of callbacks (cooperative lightweight threads as seen in frameworks like gevent are sometimes called coroutines as well, but in Tornado all coroutines use explicit context switches and are called as asynchronous functions).

Coroutines are almost as simple as synchronous code, but without the expense of a thread. They also make concurrency easier to reason about by reducing the number of places where a context switch can happen.

Example:

async def fetch_coroutine(url):
    http_client = AsyncHTTPClient()
    response = await http_client.fetch(url)
    return response.body

6.1. User’s guide
Native vs decorated coroutines

Python 3.5 introduced the `async` and `await` keywords (functions using these keywords are also called “native coroutines”). For compatibility with older versions of Python, you can use “decorated” or “yield-based” coroutines using the `tornado.gen.coroutine` decorator.

Native coroutines are the recommended form whenever possible. Only use decorated coroutines when compatibility with older versions of Python is required. Examples in the Tornado documentation will generally use the native form.

Translation between the two forms is generally straightforward:

```python
# Decorated: # Native:
# Normal function declaration # "async def" keywords
@gen.coroutine
def a():
    # "yield" all async funcs # "await" all async funcs
    b = yield c()
    b = await c()
    # "return" and "yield" # cannot be mixed in
    # Python 2, so raise a
    # special exception. # Return normally
    raise gen.Return(b)
    return b
```

Other differences between the two forms of coroutine are outlined below.

- **Native coroutines:**
  - are generally faster.
  - can use `async for` and `async with` statements which make some patterns much simpler.
  - do not run at all unless you `await` or `yield` them. Decorated coroutines can start running “in the background” as soon as they are called. Note that for both kinds of coroutines it is important to use `await` or `yield` so that any exceptions have somewhere to go.

- **Decorated coroutines:**
  - have additional integration with the `concurrent.futures` package, allowing the result of `executor.submit` to be yielded directly. For native coroutines, use `IOLoop.run_in_executor` instead.
  - support some shorthand for waiting on multiple objects by yielding a list or dict. Use `tornado.gen.multi` to do this in native coroutines.
  - can support integration with other packages including Twisted via a registry of conversion functions. To access this functionality in native coroutines, use `tornado.gen.convert_yielded`.
  - always return a `Future` object. Native coroutines return an `awaitable` object that is not a `Future`. In Tornado the two are mostly interchangeable.
How it works

This section explains the operation of decorated coroutines. Native coroutines are conceptually similar, but a little more complicated because of the extra integration with the Python runtime.

A function containing `yield` is a **generator**. All generators are asynchronous; when called they return a generator object instead of running to completion. The `@gen.coroutine` decorator communicates with the generator via the `yield` expressions, and with the coroutine’s caller by returning a **Future**.

Here is a simplified version of the coroutine decorator’s inner loop:

```python
# Simplified inner loop of tornado.gen.Runner
def run(self):
    # send(x) makes the current yield return x.
    # It returns when the next yield is reached
    future = self.gen.send(self.next)
    def callback(f):
        self.next = f.result()
        self.run()
    future.add_done_callback(callback)
```

The decorator receives a **Future** from the generator, waits (without blocking) for that **Future** to complete, then “unwraps” the **Future** and sends the result back into the generator as the result of the `yield` expression. Most asynchronous code never touches the **Future** class directly except to immediately pass the **Future** returned by an asynchronous function to a `yield` expression.

How to call a coroutine

Coroutines do not raise exceptions in the normal way: any exception they raise will be trapped in the awaitable object until it is yielded. This means it is important to call coroutines in the right way, or you may have errors that go unnoticed:

```python
async def divide(x, y):
    return x / y

def bad_call():
    # This should raise a ZeroDivisionError, but it won't because
    # the coroutine is called incorrectly.
    divide(1, 0)
```

In nearly all cases, any function that calls a coroutine must be a coroutine itself, and use the `await` or `yield` keyword in the call. When you are overriding a method defined in a superclass, consult the documentation to see if coroutines are allowed (the documentation should say that the method “may be a coroutine” or “may return a **Future**”):

```python
async def good_call():
    # await will unwrap the object returned by divide() and raise
    # the exception.
    await divide(1, 0)
```

Sometimes you may want to “fire and forget” a coroutine without waiting for its result. In this case it is recommended to use `IOLoop.spawn_callback`, which makes the **IOLoop** responsible for the call. If it fails, the **IOLoop** will log a stack trace:

```python
# The IOLoop will catch the exception and print a stack trace in
# the logs. Note that this doesn't look like a normal call, since
```

(continues on next page)
Using `IOLoop.spawn_callback` in this way is recommended for functions using `@gen.coroutine`, but it is required for functions using `async def` (otherwise the coroutine runner will not start).

Finally, at the top level of a program, if the `IOLoop is not yet running`, you can start the `IOLoop`, run the coroutine, and then stop the `IOLoop` with the `IOLoop.run_sync` method. This is often used to start the main function of a batch-oriented program:

```python
# run_sync() doesn't take arguments, so we must wrap the
# call in a lambda.
IOLoop.current().run_sync(lambda: divide(1, 0))
```

**Coroutine patterns**

**Calling blocking functions**

The simplest way to call a blocking function from a coroutine is to use `IOLoop.run_in_executor`, which returns Futures that are compatible with coroutines:

```python
async def call_blocking():
    await IOLoop.current().run_in_executor(None, blocking_func, args)
```

**Parallelism**

The `multi` function accepts lists and dicts whose values are Futures, and waits for all of those Futures in parallel:

```python
from tornado.gen import multi

async def parallel_fetch(url1, url2):
    resp1, resp2 = await multi([http_client.fetch(url1), http_client.fetch(url2)])

async def parallel_fetch_many(urls):
    responses = await multi([http_client.fetch(url) for url in urls])
    # responses is a list of HTTPResponses in the same order

async def parallel_fetch_dict(urls):
    responses = await multi({url: http_client.fetch(url) for url in urls})
    # responses is a dict {url: HTTPResponse}
```

In decorated coroutines, it is possible to yield the list or dict directly:

```python
@gen.coroutine
def parallel_fetch_decorated(url1, url2):
    resp1, resp2 = yield [http_client.fetch(url1), http_client.fetch(url2)]
```
### Interleaving

Sometimes it is useful to save a `Future` instead of yielding it immediately, so you can start another operation before waiting.

```python
from tornado.gen import convert_yielded

async def get(self):
    # convert_yielded() starts the native coroutine in the background.
    # This is equivalent to asyncio.ensure_future() (both work in Tornado).
    fetch_future = convert_yielded(self.fetch_next_chunk())
    while True:
        chunk = await fetch_future
        if chunk is None:
            break
        self.write(chunk)
        fetch_future = convert_yielded(self.fetch_next_chunk())
        await self.flush()
```

This is a little easier to do with decorated coroutines, because they start immediately when called:

```python
@gen.coroutine
def get(self):
    fetch_future = self.fetch_next_chunk()
    while True:
        chunk = yield fetch_future
        if chunk is None:
            break
        self.write(chunk)
        fetch_future = self.fetch_next_chunk()
        yield self.flush()
```

### Looping

In native coroutines, `async for` can be used. In older versions of Python, looping is tricky with coroutines since there is no way to `yield` on every iteration of a `for` or `while` loop and capture the result of the yield. Instead, you’ll need to separate the loop condition from accessing the results, as in this example from Motor:

```python
import motor
db = motor.MotorClient().test

@gen.coroutine
def loop_example(collection):
    cursor = db.collection.find()
    while (yield cursor.fetch_next):
        doc = cursor.next_object()
```
Running in the background

As an alternative to PeriodicCallback, a coroutine can contain a while True: loop and use tornado.gen.sleep:

```python
async def minute_loop():
    while True:
        await do_something()
        await gen.sleep(60)

# Coroutines that loop forever are generally started with
# spawn_callback().
IOLoop.current().spawn_callback(minute_loop)
```

Sometimes a more complicated loop may be desirable. For example, the previous loop runs every \(60+N\) seconds, where \(N\) is the running time of do_something(). To run exactly every 60 seconds, use the interleaving pattern from above:

```python
async def minute_loop2():
    while True:
        nxt = gen.sleep(60)  # Start the clock.
        await do_something()  # Run while the clock is ticking.
        await nxt  # Wait for the timer to run out.
```

6.1.4 Queue example - a concurrent web spider

Tornado’s tornado.queues module (and the very similar Queue classes in asyncio) implements an asynchronous producer / consumer pattern for coroutines, analogous to the pattern implemented for threads by the Python standard library’s queue module.

A coroutine that yields Queue.get pauses until there is an item in the queue. If the queue has a maximum size set, a coroutine that yields Queue.put pauses until there is room for another item.

A Queue maintains a count of unfinished tasks, which begins at zero. put increments the count; task_done decrements it.

In the web-spider example here, the queue begins containing only base_url. When a worker fetches a page it parses the links and puts new ones in the queue, then calls task_done to decrement the counter once. Eventually, a worker fetches a page whose URLs have all been seen before, and there is also no work left in the queue. Thus that worker’s call to task_done decrements the counter to zero. The main coroutine, which is waiting for join, is unpaused and finishes.

```python
#!/usr/bin/env python3

import asyncio
import time
from datetime import timedelta
from html.parser import HTMLParser
from urllib.parse import urljoin, urldefrag
from tornado import gen, httpclient, queues

concurrency = 10
```
async def get_links_from_url(url):
    """Download the page at `url` and parse it for links.

    Returned links have had the fragment after `#` removed, and have been made
    absolute so, e.g. the URL `gen.html#tornado.gen.coroutine` becomes
    """
    response = await httpclient.AsyncHTTPClient().fetch(url)
    print("fetched %s" % url)

    html = response.body.decode(errors="ignore")
    return [urljoin(url, remove_fragment(new_url)) for new_url in get_links(html)]

def remove_fragment(url):
    pure_url, frag = urldefrag(url)
    return pure_url

def get_links(html):
    class URLSeeker(HTMLParser):
        def __init__(self):
            HTMLParser.__init__(self)
            self.urls = []

        def handle_starttag(self, tag, attrs):
            href = dict(attrs).get("href")
            if href and tag == "a":
                self.urls.append(href)

    url_seeker = URLSeeker()
    url_seeker.feed(html)
    return url_seeker.urls

async def main():
    q = queues.Queue()
    start = time.time()
    fetching, fetched, dead = set(), set(), set()

    async def fetch_url(current_url):
        if current_url in fetching:
            return

        print("fetching %s" % current_url)
        fetching.add(current_url)
        urls = await get_links_from_url(current_url)
        fetched.add(current_url)

        for new_url in urls:
            # Only follow links beneath the base URL

(continues on next page)
if new_url.startswith(base_url):
    await q.put(new_url)

async def worker():
    async for url in q:
        if url is None:
            return
        try:
            await fetch_url(url)
        except Exception as e:
            print("Exception: %s %s" % (e, url))
            dead.add(url)
        finally:
            q.task_done()

await q.put(base_url)

# Start workers, then wait for the work queue to be empty.
workers = gen.multi([worker() for _ in range(concurrency)])
await q.join(timeout=timedelta(seconds=300))
assert fetching == (fetched | dead)
print("Done in %d seconds, fetched %s URLs." % (time.time() - start, len(fetched)))
print("Unable to fetch %s URLs." % len(dead))

# Signal all the workers to exit.
for _ in range(concurrency):
    await q.put(None)
await workers

if __name__ == "__main__":
    asyncio.run(main())

---

6.1.5 Structure of a Tornado web application

A Tornado web application generally consists of one or more `RequestHandler` subclasses, an `Application` object which routes incoming requests to handlers, and a `main()` function to start the server.

A minimal “hello world” example looks something like this:

```python
import asyncio
import tornado

class MainHandler(tornado.web.RequestHandler):
    def get(self):
        self.write("Hello, world")

def make_app():
    return tornado.web.Application(["(" + str(tornado.web) + ", MainHandler),
```

(continues on next page)
async def main():
    app = make_app()
    app.listen(8888)
    shutdown_event = asyncio.Event()
    await shutdown_event.wait()

    if __name__ == "__main__":
        asyncio.run(main())

The main coroutine

Beginning with Tornado 6.2 and Python 3.10, the recommended pattern for starting a Tornado application is to create a main coroutine to be run with asyncio.run. (In older versions, it was common to do initialization in a regular function and then start the event loop with IOLoop.current().start(). However, this pattern produces deprecation warnings starting in Python 3.10 and will break in some future version of Python.)

When the main function returns, the program exits, so most of the time for a web server main should run forever. Waiting on an asyncio.Event whose set() method is never called is a convenient way to make an asynchronous function run forever. (and if you wish to have main exit early as a part of a graceful shutdown procedure, you can call shutdown_event.set() to make it exit).

The Application object

The Application object is responsible for global configuration, including the routing table that maps requests to handlers.

The routing table is a list of URLSpec objects (or tuples), each of which contains (at least) a regular expression and a handler class. Order matters; the first matching rule is used. If the regular expression contains capturing groups, these groups are the path arguments and will be passed to the handler’s HTTP method. If a dictionary is passed as the third element of the URLSpec, it supplies the initialization arguments which will be passed to RequestHandler.initialize. Finally, the URLSpec may have a name, which will allow it to be used with RequestHandler.reverse_url.

For example, in this fragment the root URL / is mapped to MainHandler and URLs of the form /story/ followed by a number are mapped to StoryHandler. That number is passed (as a string) to StoryHandler.get.

class MainHandler(RequestHandler):
    def get(self):
        self.write('"<a href="%s">link to story 1</a>"' %
                   self.reverse_url("story", "1"))

class StoryHandler(RequestHandler):
    def initialize(self, db):
        self.db = db

    def get(self, story_id):
        self.write("this is story %s" % story_id)

app = Application([
    url(r"/", MainHandler),
    url(r"/story/(\d+)"), StoryHandler, dict(db=db), name="story")])

6.1. User's guide 23
The `Application` constructor takes many keyword arguments that can be used to customize the behavior of the application and enable optional features; see `Application.settings` for the complete list.

## Subclassing `RequestHandler`

Most of the work of a Tornado web application is done in subclasses of `RequestHandler`. The main entry point for a handler subclass is a method named after the HTTP method being handled: `get()`, `post()`, etc. Each handler may define one or more of these methods to handle different HTTP actions. As described above, these methods will be called with arguments corresponding to the capturing groups of the routing rule that matched.

Within a handler, call methods such as `RequestHandler.render` or `RequestHandler.write` to produce a response. `render()` loads a Template by name and renders it with the given arguments. `write()` is used for non-template-based output; it accepts strings, bytes, and dictionaries (dicts will be encoded as JSON).

Many methods in `RequestHandler` are designed to be overridden in subclasses and be used throughout the application. It is common to define a `BaseHandler` class that overrides methods such as `write_error` and `get_current_user` and then subclass your own `BaseHandler` instead of `RequestHandler` for all your specific handlers.

## Handling request input

The request handler can access the object representing the current request with `self.request`. See the class definition for `HTTPServerRequest` for a complete list of attributes.

Request data in the formats used by HTML forms will be parsed for you and is made available in methods like `get_query_argument` and `get_body_argument`.

```python
class MyFormHandler(tornado.web.RequestHandler):
    def get(self):
        self.write(''"\n        \'<html><body><form action="/myform" method="POST">
        \'\n        \ '<input type="text" name="message">
        \n        \ '</form></body></html>"

    def post(self):
        self.set_header("Content-Type", "text/plain")
        self.write("You wrote " + self.get_body_argument("message"))
```

Since the HTML form encoding is ambiguous as to whether an argument is a single value or a list with one element, `RequestHandler` has distinct methods to allow the application to indicate whether or not it expects a list. For lists, use `get_query_arguments` and `get_body_arguments` instead of their singular counterparts.

Files uploaded via a form are available in `self.request.files`, which maps names (the name of the HTML `<input type="file">` element) to a list of files. Each file is a dictionary of the form `{"filename":..., "content_type":..., "body":...}`. The files object is only present if the files were uploaded with a form wrapper (i.e. a `multipart/form-data` Content-Type); if this format was not used the raw uploaded data is available in `self.request.body`. By default uploaded files are fully buffered in memory; if you need to handle files that are too large to comfortably keep in memory see the `stream_request_body` class decorator.

In the demos directory, `file_receiver.py` shows both methods of receiving file uploads.

Due to the quirks of the HTML form encoding (e.g. the ambiguity around singular versus plural arguments), Tornado does not attempt to unify form arguments with other types of input. In particular, we do not parse JSON request bodies. Applications that wish to use JSON instead of form-encoding may override `prepare` to parse their requests:
def prepare(self):
    if self.request.headers.get("Content-Type", "").startswith("application/json"):
        self.json_args = json.loads(self.request.body)
    else:
        self.json_args = None

Overriding RequestHandler methods

In addition to `get()`/`post()`/etc, certain other methods in `RequestHandler` are designed to be overridden by subclasses when necessary. On every request, the following sequence of calls takes place:

1. A new `RequestHandler` object is created on each request.
2. `initialize()` is called with the initialization arguments from the `Application` configuration. `initialize` should typically just save the arguments passed into member variables; it may not produce any output or call methods like `send_error`.
3. `prepare()` is called. This is most useful in a base class shared by all of your handler subclasses, as `prepare` is called no matter which HTTP method is used. `prepare` may produce output; if it calls `finish` (or `redirect`, etc), processing stops here.
4. One of the HTTP methods is called: `get()`, `post()`, `put()`, etc. If the URL regular expression contains capturing groups, they are passed as arguments to this method.
5. When the request is finished, `on_finish()` is called. This is generally after `get()` or another HTTP method returns.

All methods designed to be overridden are noted as such in the `RequestHandler` documentation. Some of the most commonly overridden methods include:

- `write_error` - outputs HTML for use on error pages.
- `on_connection_close` - called when the client disconnects; applications may choose to detect this case and halt further processing. Note that there is no guarantee that a closed connection can be detected promptly.
- `get_current_user` - see User authentication.
- `get_user_locale` - returns `Locale` object to use for the current user.
- `set_default_headers` - may be used to set additional headers on the response (such as a custom `Server` header).

Error Handling

If a handler raises an exception, Tornado will call `RequestHandler.write_error` to generate an error page. `tornado.web.HTTPError` can be used to generate a specified status code; all other exceptions return a 500 status.

The default error page includes a stack trace in debug mode and a one-line description of the error (e.g. “500: Internal Server Error”) otherwise. To produce a custom error page, override `RequestHandler.write_error` (probably in a base class shared by all your handlers). This method may produce output normally via methods such as `write` and `render`. If the error was caused by an exception, an `exc_info` triple will be passed as a keyword argument (note that this exception is not guaranteed to be the current exception in `sys.exc_info`, so `write_error` must use e.g. `traceback.format_exception` instead of `traceback.format_exc`).

It is also possible to generate an error page from regular handler methods instead of `write_error` by calling `set_status`, writing a response, and returning. The special exception `tornado.web.Finish` may be raised to terminate the handler without calling `write_error` in situations where simply returning is not convenient.
For 404 errors, use the `default_handler_class` *Application setting*. This handler should override `prepare` instead of a more specific method like `get()` so it works with any HTTP method. It should produce its error page as described above: either by raising a `HTTPError(404)` and overriding `write_error`, or calling `self.set_status(404)` and producing the response directly in `prepare()`.

**Redirection**

There are two main ways you can redirect requests in Tornado: `RequestHandler.redirect` and with the `RedirectHandler`.

You can use `self.redirect()` within a `RequestHandler` method to redirect users elsewhere. There is also an optional parameter `permanent` which you can use to indicate that the redirection is considered permanent. The default value of `permanent` is `False`, which generates a 302 Found HTTP response code and is appropriate for things like redirecting users after successful POST requests. If `permanent` is `True`, the 301 Moved Permanently HTTP response code is used, which is useful for e.g. redirecting to a canonical URL for a page in an SEO-friendly manner.

`RedirectHandler` lets you configure redirects directly in your *Application* routing table. For example, to configure a single static redirect:

```python
app = tornado.web.Application([  
    url(r"/app", tornado.web.RedirectHandler,
        dict(url="http://itunes.apple.com/my-app-id")),  
])
```

`RedirectHandler` also supports regular expression substitutions. The following rule redirects all requests beginning with `/pictures/` to the prefix `/photos/` instead:

```python
app = tornado.web.Application([  
    url(r"/photos/(.*)", MyPhotoHandler),  
    url(r"/pictures/(.*)", tornado.web.RedirectHandler,  
        dict(url=r"/photos/{0}")),  
])
```

Unlike `RequestHandler.redirect`, `RedirectHandler` uses permanent redirects by default. This is because the routing table does not change at runtime and is presumed to be permanent, while redirects found in handlers are likely to be the result of other logic that may change. To send a temporary redirect with a `RedirectHandler`, add `permanent=False` to the `RedirectHandler` initialization arguments.

**Asynchronous handlers**

Certain handler methods (including `prepare()` and the HTTP verb methods `get()`/`post()`/etc) may be overridden as coroutines to make the handler asynchronous.

For example, here is a simple handler using a coroutine:

```python
class MainHandler(tornado.web.RequestHandler):
    async def get(self):  
        http = tornado.httpclient.AsyncHTTPClient()  
        response = await http.fetch("http://friendfeed-api.com/v2/feed/bret")  
        json = tornado.escape.json_decode(response.body)  
        self.write("Fetched " + str(len(json["entries"])) + " entries "  
                   + "from the FriendFeed API")
```
For a more advanced asynchronous example, take a look at the chat example application, which implements an AJAX chat room using long polling. Users of long polling may want to override on_connection_close() to clean up after the client closes the connection (but see that method’s docstring for caveats).

6.1.6 Templates and UI

Tornado includes a simple, fast, and flexible templating language. This section describes that language as well as related issues such as internationalization.

Tornado can also be used with any other Python template language, although there is no provision for integrating these systems into RequestHandler.render. Simply render the template to a string and pass it to RequestHandler.write.

Configuring templates

By default, Tornado looks for template files in the same directory as the .py files that refer to them. To put your template files in a different directory, use the template_path Application setting (or override RequestHandler.get_template_path if you have different template paths for different handlers).

To load templates from a non-filesystem location, subclass tornado.template.BaseLoader and pass an instance as the template_loader application setting.

Compiled templates are cached by default; to turn off this caching and reload templates so changes to the underlying files are always visible, use the application settings compiled_template_cache=False or debug=True.

Template syntax

A Tornado template is just HTML (or any other text-based format) with Python control sequences and expressions embedded within the markup:

```html
<html>
<head>
  <title>{{ title }}</title>
</head>
<body>
<ul>
  {% for item in items %}
  <li>{{ escape(item) }}</li>
  {% end %}
</ul>
</body>
</html>
```

If you saved this template as “template.html” and put it in the same directory as your Python file, you could render this template with:

```python
class MainHandler(tornado.web.RequestHandler):
  def get(self):
    items = ["Item 1", "Item 2", "Item 3"]
    self.render("template.html", title="My title", items=items)
```

Tornado templates support control statements and expressions. Control statements are surrounded by {% and %}, e.g. {% if len(items) > 2 %}. Expressions are surrounded by {{ and }}, e.g. {{ items[0] }}.
Control statements more or less map exactly to Python statements. We support if, for, while, and try, all of which are terminated with {%- end %}. We also support template inheritance using the extends and block statements, which are described in detail in the documentation for the tornado.template.

Expressions can be any Python expression, including function calls. Template code is executed in a namespace that includes the following objects and functions. (Note that this list applies to templates rendered using RequestHandler.render and render_string. If you’re using the tornado.template module directly outside of a RequestHandler many of these entries are not present).

- escape: alias for tornado.escape.xhtml_escape
- xhtml_escape: alias for tornado.escape.xhtml_escape
- url_escape: alias for tornado.escape.url_escape
- json_encode: alias for tornado.escape.json_encode
- squeeze: alias for tornado.escape.squeeze
- linkify: alias for tornado.escape.linkify
- datetime: the Python datetime module
- handler: the current RequestHandler object
- request: alias for handler.request
- current_user: alias for handler.current_user
- locale: alias for handler.locale
- _: alias for handler.locale.translate
- static_url: alias for handler.static_url
- xsrf_form_html: alias for handler.xsrf_form_html
- reverse_url: alias for Application.reverse_url
- All entries from the ui_methods and ui_modules Application settings
- Any keyword arguments passed to render or render_string

When you are building a real application, you are going to want to use all of the features of Tornado templates, especially template inheritance. Read all about those features in the tornado.template section (some features, including UI Modules are implemented in the tornado.web module).

Under the hood, Tornado templates are translated directly to Python. The expressions you include in your template are copied verbatim into a Python function representing your template. We don’t try to prevent anything in the template language; we created it explicitly to provide the flexibility that other, stricter templating systems prevent. Consequently, if you write random stuff inside of your template expressions, you will get random Python errors when you execute the template.

All template output is escaped by default, using the tornado.escape.xhtml_escape function. This behavior can be changed globally by passing autoescape=’None’ to the Application or tornado.template.Loader constructors, for a template file with the {%- autoescape None %} directive, or for a single expression by replacing {{ ... }} with {%- raw ...%}. Additionally, in each of these places the name of an alternative escaping function may be used instead of None.

Note that while Tornado’s automatic escaping is helpful in avoiding XSS vulnerabilities, it is not sufficient in all cases. Expressions that appear in certain locations, such as in JavaScript or CSS, may need additional escaping. Additionally, either care must be taken to always use double quotes and xhtml_escape in HTML attributes that may contain untrusted content, or a separate escaping function must be used for attributes (see e.g. this blog post).
Internationalization

The locale of the current user (whether they are logged in or not) is always available as `self.locale` in the request handler and as `locale` in templates. The name of the locale (e.g., `en_US`) is available as `locale.name`, and you can translate strings with the `Locale.translate` method. Templates also have the global function call `_()` available for string translation. The translate function has two forms:

```
_("Translate this string")
```

which translates the string directly based on the current locale, and:

```
_("A person liked this", "%(num)d people liked this",
 len(people)) % {'num': len(people)}
```

which translates a string that can be singular or plural based on the value of the third argument. In the example above, a translation of the first string will be returned if `len(people)` is 1, or a translation of the second string will be returned otherwise.

The most common pattern for translations is to use Python named placeholders for variables (the `%d` in the example above) since placeholders can move around on translation.

Here is a properly internationalized template:

```
<html>
  <head>
    <title>FriendFeed - {{ _("Sign in") }}</title>
  </head>
  <body>
    <form action="{{ request.path }}" method="post">
      <div>{{ _("Username") }} <input type="text" name="username"></div>
      <div>{{ _("Password") }} <input type="password" name="password"></div>
      <div><input type="submit" value="{{ _("Sign in") }}"></div>
    </form>
  </body>
</html>
```

By default, we detect the user’s locale using the `Accept-Language` header sent by the user’s browser. We choose `en_US` if we can’t find an appropriate `Accept-Language` value. If you let user’s set their locale as a preference, you can override this default locale selection by overriding `RequestHandler.get_user_locale`:

```
class BaseHandler(tornado.web.RequestHandler):
    def get_current_user(self):
        user_id = self.get_signed_cookie("user")
        if not user_id: return None
        return self.backend.get_user_by_id(user_id)

    def get_user_locale(self):
        if "locale" not in self.current_user.prefs:
            # Use the Accept-Language header
            return None
        return self.current_user.prefs["locale"]
```

If `get_user_locale` returns `None`, we fall back on the `Accept-Language` header.

The `tornado.locale` module supports loading translations in two formats: the `.mo` format used by `gettext`
Tornado supports **UI modules** to make it easy to support standard, reusable UI widgets across your application. UI modules are like special function calls to render components of your page, and they can come packaged with their own CSS and JavaScript.

For example, if you are implementing a blog, and you want to have blog entries appear on both the blog home page and on each blog entry page, you can make an **Entry** module to render them on both pages. First, create a Python module for your UI modules, e.g. `uimodules.py`:

```python
from tornado.web import UIModule

class Entry(tornado.web.UIModule):
    def render(self, entry, show_comments=False):
        return self.render_string(
            "module-entry.html", entry=entry, show_comments=show_comments)
```

Tell Tornado to use `uimodules.py` using the `ui_modules` setting in your application:

```python
settings = {
    "ui_modules": uimodules,
}
application = tornado.web.Application([  
    (r"/", HomeHandler),  
    (r"/entry/([0-9]+)"), EntryHandler),
], **settings)
```

Within a template, you can call a module with the `{% module %}` statement. For example, you could call the **Entry** module from both `home.html`:

```latex
{% for entry in entries %}
  {% module Entry(entry) %}
{% end %}
```

and `entry.html`:

```latex
30 Chapter 6. Documentation
Modules can include custom CSS and JavaScript functions by overriding the `embedded_css`, `embedded_javascript`, `javascript_files`, or `css_files` methods:

```python
class Entry(tornado.web.UIModule):
    def embedded_css(self):
        return "\n    def render(self, entry, show_comments=False):
        return self.render_string(
            "module-entry.html", show_comments=show_comments)
```

Module CSS and JavaScript will be included once no matter how many times a module is used on a page. CSS is always included in the `<head>` of the page, and JavaScript is always included just before the `</body>` tag at the end of the page.

When additional Python code is not required, a template file itself may be used as a module. For example, the preceding example could be rewritten to put the following in `module-entry.html`:

```html
{{ set_resources(embedded_css="\n" }}
<!-- more template html... -->
```

This revised template module would be invoked with:

```html
{% module Template("module-entry.html", show_comments=True) %}
```

The `set_resources` function is only available in templates invoked via `{% module Template(...) %}`. Unlike the `{% include ... %}` directive, template modules have a distinct namespace from their containing template - they can only see the global template namespace and their own keyword arguments.

## 6.1.7 Authentication and security

### Cookies and signed cookies

You can set cookies in the user's browser with the `set_cookie` method:

```python
class MainHandler(tornado.web.RequestHandler):
    def get(self):
        if not self.get_cookie("mycookie"):
            self.set_cookie("mycookie", "myvalue")
            self.write("Your cookie was not set yet!")
        else:
            self.write("Your cookie was set!")
```

Cookies are not secure and can easily be modified by clients. If you need to set cookies to, e.g., identify the currently logged in user, you need to sign your cookies to prevent forgery. Tornado supports signed cookies with the `set_signed_cookie` and `get_signed_cookie` methods. To use these methods, you need to specify a secret key named `cookie_secret` when you create your application. You can pass in application settings as keyword arguments to your application:

```python
application = tornado.web.Application([
    (r"/", MainHandler),
], cookie_secret="__TODO:_GENERATE_YOUR_OWN_RANDOM_VALUE_HERE__")
```
Signed cookies contain the encoded value of the cookie in addition to a timestamp and an HMAC signature. If the cookie is old or if the signature doesn’t match, get_signed_cookie will return None just as if the cookie isn’t set. The secure version of the example above:

```python
class MainHandler(tornado.web.RequestHandler):
    def get(self):
        if not self.get_signed_cookie("mycookie"):  
            self.set_signed_cookie("mycookie", "myvalue")
            self.write("Your cookie was not set yet!")
        else:
            self.write("Your cookie was set!")
```

Tornado’s signed cookies guarantee integrity but not confidentiality. That is, the cookie cannot be modified but its contents can be seen by the user. The cookie_secret is a symmetric key and must be kept secret – anyone who obtains the value of this key could produce their own signed cookies.

By default, Tornado’s signed cookies expire after 30 days. To change this, use the expires_days keyword argument to set_signed_cookie and the max_age_days argument to get_signed_cookie. These two values are passed separately so that you may e.g. have a cookie that is valid for 30 days for most purposes, but for certain sensitive actions (such as changing billing information) you use a smaller max_age_days when reading the cookie.

Tornado also supports multiple signing keys to enable signing key rotation. cookie_secret then must be a dict with integer key versions as keys and the corresponding secrets as values. The currently used signing key must then be set as key_version application setting but all other keys in the dict are allowed for cookie signature validation, if the correct key version is set in the cookie. To implement cookie updates, the current signing key version can be queried via get_signed_cookie_key_version.

**User authentication**

The currently authenticated user is available in every request handler as self.current_user, and in every template as current_user. By default, current_user is None.

To implement user authentication in your application, you need to override the get_current_user() method in your request handlers to determine the current user based on, e.g., the value of a cookie. Here is an example that lets users log into the application simply by specifying a nickname, which is then saved in a cookie:

```python
class BaseHandler(tornado.web.RequestHandler):
    def get_current_user(self):
        return self.get_signed_cookie("user")

class MainHandler(BaseHandler):
    def get(self):
        if not self.current_user:
            self.redirect("/login")
        return
        name = tornado.escape.xhtml_escape(self.current_user)
        self.write("Hello, " + name)

class LoginHandler(BaseHandler):
    def get(self):
        self.write("<html><body><form action="/login" method="post"> 
        'Name: <input type="text" name="name">' 
        '<input type="submit" value="Sign in">' 
        '</form></body></html>")
```

(continues on next page)
def post(self):
    self.set_signed_cookie("user", self.get_argument("name"))
    self.redirect("/")

application = tornado.web.Application([  
    (r"/", MainHandler),
    (r"/login", LoginHandler),
], cookie_secret="__TODO:_GENERATE_YOUR_OWN_RANDOM_VALUE_HERE__")

You can require that the user be logged in using the Python decorator `tornado.web.authenticated`. If a request goes to a method with this decorator, and the user is not logged in, they will be redirected to `login_url` (another application setting). The example above could be rewritten:

```python
class MainHandler(BaseHandler):
    @tornado.web.authenticated
def get(self):
        name = tornado.escape.xhtml_escape(self.current_user)
        self.write("Hello, " + name)

settings = {
    "cookie_secret": "__TODO:_GENERATE_YOUR_OWN_RANDOM_VALUE_HERE__",
    "login_url": "/login",
}
application = tornado.web.Application([  
    (r"/", MainHandler),
    (r"/login", LoginHandler),
], **settings)
```

If you decorate `post()` methods with the `authenticated` decorator, and the user is not logged in, the server will send a 403 response. The `@authenticated` decorator is simply shorthand for `if not self.current_user: self.redirect()` and may not be appropriate for non-browser-based login schemes.

Checkout the Tornado Blog example application for a complete example that uses authentication (and stores user data in a PostgreSQL database).

**Third party authentication**

The `tornado.auth` module implements the authentication and authorization protocols for a number of the most popular sites on the web, including Google/Gmail, Facebook, Twitter, and FriendFeed. The module includes methods to log users in via these sites and, where applicable, methods to authorize access to the services so you can, e.g., download a user’s address book or publish a Twitter message on their behalf.

Here is an example handler that uses Google for authentication, saving the Google credentials in a cookie for later access:

```python
class GoogleOAuth2LoginHandler(tornado.web.RequestHandler,  
tornado.auth.GoogleOAuth2Mixin):
    async def get(self):
        if self.get_argument('code', False):
            user = await self.get_authenticated_user(
                redirect_uri='http://your.site.com/auth/google',
                code=self.get_argument('code'))
```

(continues on next page)
See the tornado.auth module documentation for more details.

## Cross-site request forgery protection

Cross-site request forgery, or XSRF, is a common problem for personalized web applications.

The generally accepted solution to prevent XSRF is to cookie every user with an unpredictable value and include that value as an additional argument with every form submission on your site. If the cookie and the value in the form submission do not match, then the request is likely forged.

Tornado comes with built-in XSRF protection. To include it in your site, include the application setting xsrf_cookies:

```python
settings = {
    "cookie_secret": "__TODO:_GENERATE_YOUR_OWN_RANDOM_VALUE_HERE__",
    "login_url": "/login",
    "xsrf_cookies": True,
}
application = tornado.web.Application([  
    (r""/", MainHandler),  
    (r"/login", LoginHandler),  
], **settings)
```

If xsrf_cookies is set, the Tornado web application will set the _xsrf cookie for all users and reject all POST, PUT, and DELETE requests that do not contain a correct _xsrf value. If you turn this setting on, you need to instrument all forms that submit via POST to contain this field. You can do this with the special UIModule xsrf_form_html(), available in all templates:

```html
<% module xsrf_form_html() %>
<form action="/new_message" method="post">
  <input type="text" name="message"/>
  <input type="submit" value="Post"/>
</form>
```

If you submit AJAX POST requests, you will also need to instrument your JavaScript to include the _xsrf value with each request. This is the jQuery function we use at FriendFeed for AJAX POST requests that automatically adds the _xsrf value to all requests:

```javascript
function getCookie(name) {
    var r = document.cookie.match("\b" + name + "=([^;]*)\b");
    return r ? r[1] : undefined;
}
jQuery.postJSON = function(url, args, callback) {
    args._xsrf = getCookie("_xsrf");
}
```

(continues on next page)
$.ajax({url: url, data: $.param(args), dataType: "text", type: "POST",
    success: function(response) {
        callback(eval("(" + response + ")");
    }));
};

For PUT and DELETE requests (as well as POST requests that do not use form-encoded arguments), the XSRF token may also be passed via an HTTP header named X-XSRFToken. The XSRF cookie is normally set when xsrf_form.html is used, but in a pure-JavaScript application that does not use any regular forms you may need to access self.xsrf_token manually (just reading the property is enough to set the cookie as a side effect).

If you need to customize XSRF behavior on a per-handler basis, you can override RequestHandler.check_xsrf_cookie(). For example, if you have an API whose authentication does not use cookies, you may want to disable XSRF protection by making check_xsrf_cookie() do nothing. However, if you support both cookie and non-cookie-based authentication, it is important that XSRF protection be used whenever the current request is authenticated with a cookie.

**DNS Rebinding**

DNS rebinding is an attack that can bypass the same-origin policy and allow external sites to access resources on private networks. This attack involves a DNS name (with a short TTL) that alternates between returning an IP address controlled by the attacker and one controlled by the victim (often a guessable private IP address such as 127.0.0.1 or 192.168.1.1).

Applications that use TLS are not vulnerable to this attack (because the browser will display certificate mismatch warnings that block automated access to the target site).

Applications that cannot use TLS and rely on network-level access controls (for example, assuming that a server on 127.0.0.1 can only be accessed by the local machine) should guard against DNS rebinding by validating the Host HTTP header. This means passing a restrictive hostname pattern to either a HostMatches router or the first argument of Application.add_handlers:

```python
# BAD: uses a default host pattern of r'.*'
app = Application([('/foo', FooHandler)])

# GOOD: only matches localhost or its ip address.
app = Application()
app.add_handlers(r'(localhost|127\.|0\.|1)',
    [('/foo', FooHandler)])

# GOOD: same as previous example using tornado.routing.
app = Application([
    (HostMatches(r'(localhost|127\.|0\.|1)'),
        [('/foo', FooHandler)]),
])
```

In addition, the default_host argument to Application and the DefaultHostMatches router must not be used in applications that may be vulnerable to DNS rebinding, because it has a similar effect to a wildcard host pattern.
6.1.8 Running and deploying

Since Tornado supplies its own HTTPServer, running and deploying it is a little different from other Python web frameworks. Instead of configuring a WSGI container to find your application, you write a `main()` function that starts the server:

```python
import asyncio

async def main():
    app = make_app()
    app.listen(8888)
    await asyncio.Event().wait()

if __name__ == '__main__':
    asyncio.run(main())
```

Configure your operating system or process manager to run this program to start the server. Please note that it may be necessary to increase the number of open files per process (to avoid “Too many open files”-Error). To raise this limit (setting it to 50000 for example) you can use the `ulimit` command, modify `/etc/security/limits.conf` or set `minfds` in your `supervisord` config.

Processes and ports

Due to the Python GIL (Global Interpreter Lock), it is necessary to run multiple Python processes to take full advantage of multi-CPU machines. Typically it is best to run one process per CPU.

The simplest way to do this is to add `reuse_port=True` to your `listen()` calls and then simply run multiple copies of your application.

Tornado also has the ability to start multiple processes from a single parent process (note that this does not work on Windows). This requires some alterations to application startup.

```python
def main():
    sockets = bind_sockets(8888)
    tornado.process.fork_processes(0)
    async def post_fork_main():
        server = TCPServer()
        server.add_sockets(sockets)
        await asyncio.Event().wait()
    asyncio.run(post_fork_main())
```

This is another way to start multiple processes and have them all share the same port, although it has some limitations. First, each child process will have its own IOLoop, so it is important that nothing touches the global IOLoop instance (even indirectly) before the fork. Second, it is difficult to do zero-downtime updates in this model. Finally, since all the processes share the same port it is more difficult to monitor them individually.

For more sophisticated deployments, it is recommended to start the processes independently, and have each one listen on a different port. The “process groups” feature of `supervisord` is one good way to arrange this. When each process uses a different port, an external load balancer such as HAProxy or nginx is usually needed to present a single address to outside visitors.
Running behind a load balancer

When running behind a load balancer like nginx, it is recommended to pass `xheaders=True` to the `HTTPServer` constructor. This will tell Tornado to use headers like `X-Real-IP` to get the user’s IP address instead of attributing all traffic to the balancer’s IP address.

This is a barebones nginx config file that is structurally similar to the one we use at FriendFeed. It assumes nginx and the Tornado servers are running on the same machine, and the four Tornado servers are running on ports 8000 - 8003:

```plaintext
user nginx;
worker_processes 1;

error_log /var/log/nginx/error.log;
pid /var/run/nginx.pid;

events {
    worker_connections 1024;
    use epoll;
}

http {
    # Enumerate all the Tornado servers here
    upstream frontends {
        server 127.0.0.1:8000;
        server 127.0.0.1:8001;
        server 127.0.0.1:8002;
        server 127.0.0.1:8003;
    }

    include /etc/nginx/mime.types;
    default_type application/octet-stream;

    access_log /var/log/nginx/access.log;

    keepalive_timeout 65;
    proxy_read_timeout 200;
    sendfile on;
    tcp_nopush on;
    tcp_nodelay on;
    gzip on;
    gzip_min_length 1000;
    gzip_proxied any;
    gzip_types text/plain text/html text/css text/xml
        application/x-javascript application/xml
        application/atom+xml text/javascript;

    # Only retry if there was a communication error, not a timeout
    # on the Tornado server (to avoid propagating "queries of death"
    # to all frontends)
    proxy_next_upstream error;

    server {
        listen 80;
        
```
# Allow file uploads
client_max_body_size 50M;

location ^~ /static/ {
    root /var/www;
    if ($query_string) {
        expires max;
    }
}

location = /favicon.ico {
    rewrite (.*) /static/favicon.ico;
}

location = /robots.txt {
    rewrite (.*) /static/robots.txt;
}

location / {
    proxy_pass_header Server;
    proxy_set_header Host $http_host;
    proxy_redirect off;
    proxy_set_header X-Real-IP $remote_addr;
    proxy_set_header X-Scheme $scheme;
    proxy_pass http://frontends;
}

Static files and aggressive file caching

You can serve static files from Tornado by specifying the static_path setting in your application:

```python
settings = {
    "static_path": os.path.join(os.path.dirname(__file__), "static"),
    "cookie_secret": "__TODO:_GENERATE_YOUR_OWN_RANDOM_VALUE_HERE__",
    "login_url": "/login",
    "xsrf_cookies": True,
}

application = tornado.web.Application([  
    (r"\", MainHandler),
    (r"/login", LoginHandler),
    (r"/(apple-touch-icon\.(png|ico))", tornado.web.StaticFileHandler,
      dict(path=settings['static_path']))),
], **settings)
```

This setting will automatically make all requests that start with /static/ serve from that static directory, e.g. http://localhost:8888/static/foo.png will serve the file foo.png from the specified static directory. We also automatically serve /robots.txt and /favicon.ico from the static directory (even though they don’t start with the /static/ prefix).

In the above settings, we have explicitly configured Tornado to serve apple-touch-icon.png from the root with the StaticFileHandler, though it is physically in the static file directory. (The capturing group in that regular expression is necessary to tell StaticFileHandler the requested filename; recall that capturing groups are passed to handlers
Tornado Documentation, Release 6.4.dev1

as method arguments.) You could do the same thing to serve e.g. sitemap.xml from the site root. Of course, you can
also avoid faking a root apple-touch-icon.png by using the appropriate <link /> tag in your HTML.
To improve performance, it is generally a good idea for browsers to cache static resources aggressively so browsers
won’t send unnecessary If-Modified-Since or Etag requests that might block the rendering of the page. Tornado
supports this out of the box with static content versioning.
To use this feature, use the static_url method in your templates rather than typing the URL of the static file directly
in your HTML:
<html>
<head>
<title>FriendFeed - {{ _("Home") }}</title>
</head>
<body>
<div><img src="{{ static_url("images/logo.png") }}"/></div>
</body>
</html>
The static_url() function will translate that relative path to a URI that looks like /static/images/logo.png?
v=aae54. The v argument is a hash of the content in logo.png, and its presence makes the Tornado server send cache
headers to the user’s browser that will make the browser cache the content indefinitely.
Since the v argument is based on the content of the file, if you update a file and restart your server, it will start sending a
new v value, so the user’s browser will automatically fetch the new file. If the file’s contents don’t change, the browser
will continue to use a locally cached copy without ever checking for updates on the server, significantly improving
rendering performance.
In production, you probably want to serve static files from a more optimized static file server like nginx. You can configure almost any web server to recognize the version tags used by static_url() and set caching headers accordingly.
Here is the relevant portion of the nginx configuration we use at FriendFeed:
location /static/ {
root /var/friendfeed/static;
if ($query_string) {
expires max;
}
}

Debug mode and automatic reloading
If you pass debug=True to the Application constructor, the app will be run in debug/development mode. In this
mode, several features intended for convenience while developing will be enabled (each of which is also available as
an individual flag; if both are specified the individual flag takes precedence):
• autoreload=True: The app will watch for changes to its source files and reload itself when anything changes.
This reduces the need to manually restart the server during development. However, certain failures (such as
syntax errors at import time) can still take the server down in a way that debug mode cannot currently recover
from.
• compiled_template_cache=False: Templates will not be cached.
• static_hash_cache=False: Static file hashes (used by the static_url function) will not be cached.
• serve_traceback=True: When an exception in a RequestHandler is not caught, an error page including a
stack trace will be generated.

6.1. User’s guide

39


Autoreload mode is not compatible with the multi-process mode of HTTPServer. You must not give HTTPServer.start an argument other than 1 (or call tornado.process.fork_processes) if you are using autoreload mode.

The automatic reloading feature of debug mode is available as a standalone module in tornado.autoreload. The two can be used in combination to provide extra robustness against syntax errors: set autoreload=True within the app to detect changes while it is running, and start it with python -m tornado.autoreload myserver.py to catch any syntax errors or other errors at startup.

Reloading loses any Python interpreter command-line arguments (e.g. -u) because it re-executes Python using sys.executable and sys.argv. Additionally, modifying these variables will cause reloading to behave incorrectly.

On some platforms (including Windows and Mac OS X prior to 10.6), the process cannot be updated “in-place”, so when a code change is detected the old server exits and a new one starts. This has been known to confuse some IDEs.

6.2 Web framework

6.2.1 tornado.web — RequestHandler and Application classes

tornado.web provides a simple web framework with asynchronous features that allow it to scale to large numbers of open connections, making it ideal for long polling.

Here is a simple “Hello, world” example app:

```python
import asyncio
import tornado

class MainHandler(tornado.web.RequestHandler):
    def get(self):
        self.write("Hello, world")

async def main():
    application = tornado.web.Application([  
        (r"/", MainHandler),
    ])
    application.listen(8888)
    await asyncio.Event().wait()

if __name__ == "__main__":
    asyncio.run(main())
```

See the User's guide for additional information.

Thread-safety notes

In general, methods on RequestHandler and elsewhere in Tornado are not thread-safe. In particular, methods such as write(), finish(), and flush() must only be called from the main thread. If you use multiple threads it is important to use IOLoop.add_callback to transfer control back to the main thread before finishing the request, or to limit your use of other threads to IOLoop.run_in_executor and ensure that your callbacks running in the executor do not refer to Tornado objects.
### Request handlers

**class**  `tornado.web.RequestHandler(...)`

Base class for HTTP request handlers.

Subclasses must define at least one of the methods defined in the “Entry points” section below.

Applications should not construct `RequestHandler` objects directly and subclasses should not override `__init__` (override `initialize` instead).

### Entry points

**RequestHandler.initialize() → None**

Hook for subclass initialization. Called for each request.

A dictionary passed as the third argument of a `URLSpec` will be supplied as keyword arguments to `initialize()`.

Example:

```python
class ProfileHandler(RequestHandler):
    def initialize(self, database):
        self.database = database

    def get(self, username):
        ...

app = Application([r'/user/(.*)', ProfileHandler, dict(database=database)],)
```

**RequestHandler.prepare() → Optional[Awaitable[None]]**

Called at the beginning of a request before `get/post/etc.`

Override this method to perform common initialization regardless of the request method.

Asynchronous support: Use `async def` or decorate this method with `gen.coroutine` to make it asynchronous. If this method returns an `Awaitable`, execution will not proceed until the `Awaitable` is done.

New in version 3.1: Asynchronous support.

**RequestHandler.on_finish() → None**

Called after the end of a request.

Override this method to perform cleanup, logging, etc. This method is a counterpart to `prepare`. on_finish may not produce any output, as it is called after the response has been sent to the client.

Implement any of the following methods (collectively known as the HTTP verb methods) to handle the corresponding HTTP method. These methods can be made asynchronous with the `async def` keyword or `gen.coroutine` decorator.

The arguments to these methods come from the `URLSpec`: Any capturing groups in the regular expression become arguments to the HTTP verb methods (keyword arguments if the group is named, positional arguments if it’s unnamed).

To support a method not on this list, override the class variable `SUPPORTED_METHODS`:

```python
class WebDAVHandler(RequestHandler):
    SUPPORTED_METHODS = RequestHandler.SUPPORTED_METHODS + ('PROPFIND',)
```

(continues on next page)
def propfind(self):
    pass

RequestHandler.get(*args: str, **kwargs: str) -> None
RequestHandler.head(*args: str, **kwargs: str) -> None
RequestHandler.post(*args: str, **kwargs: str) -> None
RequestHandler.delete(*args: str, **kwargs: str) -> None
RequestHandler.patch(*args: str, **kwargs: str) -> None
RequestHandler.put(*args: str, **kwargs: str) -> None
RequestHandler.options(*args: str, **kwargs: str) -> None

Input

The argument methods provide support for HTML form-style arguments. These methods are available in both singular and plural forms because HTML forms are ambiguous and do not distinguish between a singular argument and a list containing one entry. If you wish to use other formats for arguments (for example, JSON), parse self.request.body yourself:

def prepare(self):
    if self.request.headers['Content-Type'] == 'application/x-json':
        self.args = json_decode(self.request.body)
        # Access self.args directly instead of using self.get_argument.

RequestHandler.get_argument(name: str, default: str, strip: bool = True) -> str
RequestHandler.get_argument(name: str, default: _ArgDefaultMarker = _ARG_DEFAULT, strip: bool = True) -> str
RequestHandler.get_argument(name: str, default: None, strip: bool = True) -> Optional[str]

Returns the value of the argument with the given name.

If default is not provided, the argument is considered to be required, and we raise a MissingArgumentError if it is missing.

If the argument appears in the request more than once, we return the last value.

This method searches both the query and body arguments.

RequestHandler.get_arguments(name: str, strip: bool = True) -> List[str]

Returns a list of the arguments with the given name.

If the argument is not present, returns an empty list.

This method searches both the query and body arguments.

RequestHandler.get_query_argument(name: str, default: Union[None, str, RAISE] = RAISE, strip: bool = True) -> Optional[str]

Returns the value of the argument with the given name from the request query string.

If default is not provided, the argument is considered to be required, and we raise a MissingArgumentError if it is missing.
If the argument appears in the url more than once, we return the last value.

New in version 3.2.

```python
RequestHandler.get_query_arguments(name: str, strip: bool = True) \rightarrow List[str]
```

Returns a list of the query arguments with the given name.

If the argument is not present, returns an empty list.

New in version 3.2.

```python
RequestHandler.get_body_argument(name: str, default: Union[None, str, RAISE] = RAISE, strip: bool = True) \rightarrow Optional[str]
```

Returns the value of the argument with the given name from the request body.

If default is not provided, the argument is considered to be required, and we raise a `MissingArgumentError` if it is missing.

If the argument appears in the url more than once, we return the last value.

New in version 3.2.

```python
RequestHandler.get_body_arguments(name: str, strip: bool = True) \rightarrow List[str]
```

Returns a list of the body arguments with the given name.

If the argument is not present, returns an empty list.

New in version 3.2.

```python
RequestHandler.decode_argument(value: bytes, name: Optional[str] = None) \rightarrow str
```

Decodes an argument from the request.

The argument has been percent-decoded and is now a byte string. By default, this method decodes the argument as utf-8 and returns a unicode string, but this may be overridden in subclasses.

This method is used as a filter for both `get_argument()` and for values extracted from the url and passed to `get()/post()` etc.

The name of the argument is provided if known, but may be None (e.g. for unnamed groups in the url regex).

RequestHandler.request

The `tornado.httpserver.HTTPServerRequest` object containing additional request parameters including e.g. headers and body data.

RequestHandler.path_args

RequestHandler.path_kwargs

The `path_args` and `path_kwargs` attributes contain the positional and keyword arguments that are passed to the `HTTP verb methods`. These attributes are set before those methods are called, so the values are available during `prepare`.

RequestHandler.data_received(chunk: bytes) \rightarrow Optional[Awaitable[None]]

Implement this method to handle streamed request data.

Requires the `stream_request_body` decorator.

May be a coroutine for flow control.
Output

RequestHandler.set_status(status_code: int, reason: Optional[str] = None) → None
Sets the status code for our response.

Parameters

- **status_code** (int) – Response status code.
- **reason** (str) – Human-readable reason phrase describing the status code. If None, it will be filled in from http.client.responses or “Unknown”.

Changed in version 5.0: No longer validates that the response code is in http.client.responses.

RequestHandler.set_header(name: str, value: Union[bytes, str, int, Integral, datetime]) → None
Sets the given response header name and value.

All header values are converted to strings (datetime objects are formatted according to the HTTP specification for the Date header).

RequestHandler.add_header(name: str, value: Union[bytes, str, int, Integral, datetime]) → None
Adds the given response header and value.

Unlike set_header, add_header may be called multiple times to return multiple values for the same header.

RequestHandler.clear_header(name: str) → None
Clears an outgoing header, undoing a previous set_header call.

Note that this method does not apply to multi-valued headers set by add_header.

RequestHandler.set_default_headers() → None
Override this to set HTTP headers at the beginning of the request.

For example, this is the place to set a custom Server header. Note that setting such headers in the normal flow of request processing may not do what you want, since headers may be reset during error handling.

RequestHandler.write(chunk: Union[str, bytes, dict]) → None
Writes the given chunk to the output buffer.

To write the output to the network, use the **flush()** method below.

If the given chunk is a dictionary, we write it as JSON and set the Content-Type of the response to be application/json. (if you want to send JSON as a different Content-Type, call set_header after calling write()).

Note that lists are not converted to JSON because of a potential cross-site security vulnerability. All JSON output should be wrapped in a dictionary. More details at http://haacked.com/archive/2009/06/25/json-hijacking.aspx and https://github.com/facebook/tornado/issues/1009

RequestHandler.flush(include_footers: bool = False) → Future[None]
Flushes the current output buffer to the network.

Changed in version 4.0: Now returns a Future if no callback is given.

Changed in version 6.0: The callback argument was removed.

RequestHandler.finish(chunk: Optional[Union[str, bytes, dict]] = None) → Future[None]
Finishes this response, ending the HTTP request.

Passing a chunk to finish() is equivalent to passing that chunk to write() and then calling finish() with no arguments.
Returns a `Future` which may optionally be awaited to track the sending of the response to the client. This `Future` resolves when all the response data has been sent, and raises an error if the connection is closed before all data can be sent.

Changed in version 5.1: Now returns a `Future` instead of `None`.

```python
RequestHandler.render(template_name: str, **kwargs: Any) → Future[None]
```

Renders the template with the given arguments as the response.

`render()` calls `finish()`, so no other output methods can be called after it.

Returns a `Future` with the same semantics as the one returned by `finish`. Awaiting this `Future` is optional.

Changed in version 5.1: Now returns a `Future` instead of `None`.

```python
RequestHandler.render_string(template_name: str, **kwargs: Any) → bytes
```

Generate the given template with the given arguments.

We return the generated byte string (in utf8). To generate and write a template as a response, use `render()` above.

```python
RequestHandler.get_template_namespace() → Dict[str, Any]
```

Returns a dictionary to be used as the default template namespace.

May be overridden by subclasses to add or modify values.

The results of this method will be combined with additional defaults in the `tornado.template` module and keyword arguments to `render` or `render_string`.

```python
RequestHandler.redirect(url: str, permanent: bool = False, status: Optional[int] = None) → None
```

Sends a redirect to the given (optionally relative) URL.

If the `status` argument is specified, that value is used as the HTTP status code; otherwise either 301 (permanent) or 302 (temporary) is chosen based on the `permanent` argument. The default is 302 (temporary).

```python
RequestHandler.send_error(status_code: int = 500, **kwargs: Any) → None
```

Sends the given HTTP error code to the browser.

If `flush()` has already been called, it is not possible to send an error, so this method will simply terminate the response. If output has been written but not yet flushed, it will be discarded and replaced with the error page.

Override `write_error()` to customize the error page that is returned. Additional keyword arguments are passed through to `write_error`.

```python
RequestHandler.write_error(status_code: int, **kwargs: Any) → None
```

Override to implement custom error pages.

`write_error` may call `write`, `render`, `set_header`, etc to produce output as usual.

If this error was caused by an uncaught exception (including HTTPError), an `exc_info` triple will be available as `kwargs["exc_info"]`. Note that this exception may not be the “current” exception for purposes of methods like `sys.exc_info()` or `traceback.format_exc`.

```python
RequestHandler.clear() → None
```

Resets all headers and content for this response.

```python
RequestHandler.render_linked_js(js_files: Iterable[str]) → str
```

Default method used to render the final js links for the rendered webpage.

Override this method in a sub-classed controller to change the output.
RequestHandler.render_embed_js (js_embed: Iterable[bytes]) → bytes

Default method used to render the final embedded js for the rendered webpage.

Override this method in a sub-classed controller to change the output.

RequestHandler.render_linked_css (css_files: Iterable[str]) → str

Default method used to render the final css links for the rendered webpage.

Override this method in a sub-classed controller to change the output.

RequestHandler.render_embed_css (css_embed: Iterable[bytes]) → bytes

Default method used to render the final embedded css for the rendered webpage.

Override this method in a sub-classed controller to change the output.

Cookies

RequestHandler.cookies

An alias for self.request.cookies.

RequestHandler.get_cookie (name: str, default: Optional[str] = None) → Optional[str]

Returns the value of the request cookie with the given name.

If the named cookie is not present, returns default.

This method only returns cookies that were present in the request. It does not see the outgoing cookies set by set_cookie in this handler.

Sets an outgoing cookie name/value with the given options.

Newly-set cookies are not immediately visible via get_cookie; they are not present until the next request.

Most arguments are passed directly to http.cookies.Morsel directly. See https://developer.mozilla.org/en-US/docs/Web/HTTP/Headers/Set-Cookie for more information.

expires may be a numeric timestamp as returned by time.time, a time tuple as returned by time.gmtime, or a datetime.datetime object. expires_days is provided as a convenience to set an expiration time in days from today (if both are set, expires is used).

Deprecated since version 6.3: Keyword arguments are currently accepted case-insensitively. In Tornado 7.0 this will be changed to only accept lowercase arguments.

RequestHandler.clear_cookie (name: str, **kwargs: Any) → None

Deletes the cookie with the given name.

This method accepts the same arguments as set_cookie, except for expires and max_age. Clearing a cookie requires the same domain and path arguments as when it was set. In some cases the samesite and secure arguments are also required to match. Other arguments are ignored.

Similar to set_cookie, the effect of this method will not be seen until the following request.

Changed in version 6.3: Now accepts all keyword arguments that set_cookie does. The samesite and secure flags have recently become required for clearing samesite="none" cookies.
RequestHandler.clear_all_cookies(**kwargs: Any) → None

Attempt to delete all the cookies the user sent with this request.

See clear_cookie for more information on keyword arguments. Due to limitations of the cookie protocol, it is impossible to determine on the server side which values are necessary for the domain, path, sameSite, or secure arguments, this method can only be successful if you consistently use the same values for these arguments when setting cookies.

Similar to set_cookie, the effect of this method will not be seen until the following request.

Changed in version 3.2: Added the path and domain parameters.

Changed in version 6.3: Now accepts all keyword arguments that set_cookie does.

Deprecated since version 6.3: The increasingly complex rules governing cookies have made it impossible for a clear_all_cookies method to work reliably since all we know about cookies are their names. Applications should generally use clear_cookie one at a time instead.

RequestHandler.get_signed_cookie(name: str, value: Optional[str] = None, max_age_days: float = 31, min_version: Optional[int] = None) → Optional[bytes]

Returns the given signed cookie if it validates, or None.

The decoded cookie value is returned as a byte string (unlike get_cookie).

Similar to get_cookie, this method only returns cookies that were present in the request. It does not see outgoing cookies set by set_signed_cookie in this handler.

Changed in version 3.2.1:

- Added the min_version argument. Introduced cookie version 2; both versions 1 and 2 are accepted by default.

Changed in version 6.3: Renamed from get_secure_cookie to get_signed_cookie to avoid confusion with other uses of “secure” in cookie attributes and prefixes. The old name remains as an alias.

RequestHandler.get_signed_cookie_key_version(name: str, value: Optional[str] = None) → Optional[int]

Returns the signing key version of the secure cookie.

The version is returned as int.

Changed in version 6.3: Renamed from get_secure_cookie_key_version to set_signed_cookie_key_version to avoid confusion with other uses of “secure” in cookie attributes and prefixes. The old name remains as an alias.

RequestHandler.set_signed_cookie(name: str, value: Union[str, bytes], expires_days: Optional[float] = 30, version: Optional[int] = None, **kwargs: Any) → None

Signs and timestamps a cookie so it cannot be forged.

You must specify the cookie_secret setting in your Application to use this method. It should be a long, random sequence of bytes to be used as the HMAC secret for the signature.

To read a cookie set with this method, use get_signed_cookie().

Note that the expires_days parameter sets the lifetime of the cookie in the browser, but is independent of the max_age_days parameter to get_signed_cookie. A value of None limits the lifetime to the current browser session.

Secure cookies may contain arbitrary byte values, not just unicode strings (unlike regular cookies)

Similar to set_cookie, the effect of this method will not be seen until the following request.

Changed in version 3.2.1: Added the version argument. Introduced cookie version 2 and made it the default.
Changed in version 6.3: Renamed from `set_secure_cookie` to `set_signed_cookie` to avoid confusion with other uses of “secure” in cookie attributes and prefixes. The old name remains as an alias.

```python
RequestHandler.get_secure_cookie()
```

Deprecated alias for `get_signed_cookie`.

Deprecated since version 6.3.

```python
RequestHandler.get_secure_cookie_key_version()
```

Deprecated alias for `get_signed_cookie_key_version`.

Deprecated since version 6.3.

```python
RequestHandler.set_secure_cookie()
```

Deprecated alias for `set_signed_cookie`.

Deprecated since version 6.3.

```python
RequestHandler.create_signed_value(name: str, value: Union[str, bytes], version: Optional[int] = None) -> bytes
```

Signs and timestamps a string so it cannot be forged.

Normally used via `set_signed_cookie`, but provided as a separate method for non-cookie uses. To decode a value not stored as a cookie use the optional value argument to `get_signed_cookie`.

Changed in version 3.2.1: Added the `version` argument. Introduced cookie version 2 and made it the default.

```python
tornado.web.MIN_SUPPORTED_SIGNED_VALUE_VERSION = 1
```

The oldest signed value version supported by this version of Tornado.

Signed values older than this version cannot be decoded.

New in version 3.2.1.

```python
tornado.web.MAX_SUPPORTED_SIGNED_VALUE_VERSION = 2
```

The newest signed value version supported by this version of Tornado.

Signed values newer than this version cannot be decoded.

New in version 3.2.1.

```python
tornado.web.DEFAULT_SIGNED_VALUE_VERSION = 2
```

The signed value version produced by `RequestHandler.create_signed_value`.

May be overridden by passing a `version` keyword argument.

New in version 3.2.1.

```python
tornado.web.DEFAULT_SIGNED_VALUE_MIN_VERSION = 1
```

The oldest signed value accepted by `RequestHandler.get_signed_cookie`.

May be overridden by passing a `min_version` keyword argument.

New in version 3.2.1.
Other

RequestHandler.application

The Application object serving this request

RequestHandler.check_etag_header() → bool

Checks the Etag header against requests’s If-None-Match.

Returns True if the request’s Etag matches and a 304 should be returned. For example:

```python
self.set_etag_header()
if self.check_etag_header():
    self.set_status(304)
    return
```

This method is called automatically when the request is finished, but may be called earlier for applications that override compute_etag and want to do an early check for If-None-Match before completing the request. The Etag header should be set (perhaps with set_etag_header) before calling this method.

RequestHandler.check_xsrf_cookie() → None

Verifies that the _xsrf cookie matches the _xsrf argument.

To prevent cross-site request forgery, we set an _xsrf cookie and include the same value as a non-cookie field with all POST requests. If the two do not match, we reject the form submission as a potential forgery.

The _xsrf value may be set as either a form field named _xsrf or in a custom HTTP header named X-XSRFToken or X-CSRFToken (the latter is accepted for compatibility with Django).

See http://en.wikipedia.org/wiki/Cross-site_request_forgery

Changed in version 3.2.2: Added support for cookie version 2. Both versions 1 and 2 are supported.

RequestHandler.compute_etag() → Optional[str]

Computes the etag header to be used for this request.

By default uses a hash of the content written so far.

May be overridden to provide custom etag implementations, or may return None to disable tornado’s default etag support.

RequestHandler.create_template_loader(template_path: str) → BaseLoader

Returns a new template loader for the given path.

May be overridden by subclasses. By default returns a directory-based loader on the given path, using the autoescape and template_whitespace application settings. If a template_loader application setting is supplied, uses that instead.

RequestHandler.current_user

The authenticated user for this request.

This is set in one of two ways:

- A subclass may override get_current_user(), which will be called automatically the first time self.current_user is accessed. get_current_user() will only be called once per request, and is cached for future access:

```python
def get_current_user(self):
    user_cookie = self.get_signed_cookie("user")
    if user_cookie:
```

(continues on next page)
return json.loads(user_cookie)
return None

• It may be set as a normal variable, typically from an overridden prepare():

```python
@gen.coroutine
def prepare(self):
    user_id_cookie = self.get_signed_cookie("user_id")
    if user_id_cookie:
        self.current_user = yield load_user(user_id_cookie)
```

Note that prepare() may be a coroutine while get_current_user() may not, so the latter form is necessary if loading the user requires asynchronous operations.

The user object may be any type of the application’s choosing.

RequestHandler.detach() → IOStream
Take control of the underlying stream.
Returns the underlying IOStream object and stops all further HTTP processing. Intended for implementing protocols like websockets that tunnel over an HTTP handshake.
This method is only supported when HTTP/1.1 is used.
New in version 5.1.

RequestHandler.get_browser_locale(default: str = 'en_US') → Locale
Determines the user’s locale from Accept-Language header.
See http://www.w3.org/Protocols/rfc2616/rfc2616-sec14.html#sec14.4

RequestHandler.get_current_user() → Any
Override to determine the current user from, e.g., a cookie.
This method may not be a coroutine.

RequestHandler.get_login_url() → str
Override to customize the login URL based on the request.
By default, we use the login_url application setting.

RequestHandler.get_status() → int
Returns the status code for our response.

RequestHandler.get_template_path() → Optional[str]
Override to customize template path for each handler.
By default, we use the template_path application setting. Return None to load templates relative to the calling file.

RequestHandler.get_user_locale() → Optional[Locale]
Override to determine the locale from the authenticated user.
If None is returned, we fall back to get_browser_locale().
This method should return a tornado.locale.Locale object, most likely obtained via a call like tornado.locale.get("en")
**RequestHandler.locale**

The locale for the current session.

Determined by either `get_user_locale`, which you can override to set the locale based on, e.g., a user preference stored in a database, or `get_browser_locale`, which uses the `Accept-Language` header.

**RequestHandler.log_exception**

```python
RequestHandler.log_exception(typ: Optional[Type[BaseException]], value: Optional[BaseException], tb: Optional[TracebackType]) → None
```

Override to customize logging of uncaught exceptions.

By default logs instances of `HTTPError` as warnings without stack traces (on the `tornado.general` logger), and all other exceptions as errors with stack traces (on the `tornado.application` logger).

New in version 3.1.

**RequestHandler.on_connection_close**

```python
RequestHandler.on_connection_close() → None
```

Called in async handlers if the client closed the connection.

Override this to clean up resources associated with long-lived connections. Note that this method is called only if the connection was closed during asynchronous processing; if you need to do cleanup after every request override `on_finish` instead.

Proxies may keep a connection open for a time (perhaps indefinitely) after the client has gone away, so this method may not be called promptly after the end user closes their connection.

**RequestHandler.require_setting**

```python
RequestHandler.require_setting(name: str, feature: str = 'this feature') → None
```

Raises an exception if the given app setting is not defined.

**RequestHandler.reverse_url**

```python
RequestHandler.reverse_url(name: str, *args: Any) → str
```

Alias for `Application.reverse_url`.

**RequestHandler.set_etag_header**

```python
RequestHandler.set_etag_header() → None
```

Sets the response’s Etag header using `self.compute_etag()`.

Note: no header will be set if `compute_etag()` returns `None`.

This method is called automatically when the request is finished.

**RequestHandler.settings**

An alias for `self.application.settings`.

**RequestHandler.static_url**

```python
RequestHandler.static_url(path: str, include_host: Optional[bool] = None, **kwargs: Any) → str
```

Returns a static URL for the given relative static file path.

This method requires you set the `static_path` setting in your application (which specifies the root directory of your static files).

This method returns a versioned url (by default appending `?v=<signature>`), which allows the static files to be cached indefinitely. This can be disabled by passing `include_version=False` (in the default implementation; other static file implementations are not required to support this, but they may support other options).

By default this method returns URLs relative to the current host, but if `include_host` is true the URL returned will be absolute. If this handler has an `include_host` attribute, that value will be used as the default for all `static_url` calls that do not pass `include_host` as a keyword argument.

**RequestHandler.xsrf_form_html**

```python
RequestHandler.xsrf_form_html() → str
```

An HTML `<input/>` element to be included with all POST forms.

It defines the `_xsrf` input value, which we check on all POST requests to prevent cross-site request forgery. If you have set the `xsrf_cookies` application setting, you must include this HTML within all of your HTML forms.
In a template, this method should be called with {% module xsrf_form_html() %}

See check_xsrf_cookie() above for more information.

**RequestHandler.xsrf_token**

The XSRF-prevention token for the current user/session.

To prevent cross-site request forgery, we set an `_xsrf` cookie and include the same `_xsrf` value as an argument with all POST requests. If the two do not match, we reject the form submission as a potential forgery.

See http://en.wikipedia.org/wiki/Cross-site_request_forgery

This property is of type bytes, but it contains only ASCII characters. If a character string is required, there is no need to base64-encode it; just decode the byte string as UTF-8.

Changed in version 3.2.2: The xsrf token will now be have a random mask applied in every request, which makes it safe to include the token in pages that are compressed. See http://breachattack.com for more information on the issue fixed by this change. Old (version 1) cookies will be converted to version 2 when this method is called unless the xsrf_cookie_version Application setting is set to 1.

Changed in version 4.3: The xsrf_cookie_kwargs Application setting may be used to supply additional cookie options (which will be passed directly to set_cookie). For example, xsrf_cookie_kwargs=dict(httponly=True, secure=True) will set the secure and httponly flags on the _xsrf cookie.

**Application configuration**

```python
class tornado.web.Application(handlers: Optional[List[Union[Rule, Tuple]]] = None, default_host: Optional[str] = None, transforms: Optional[List[Type[OutputTransform]]] = None, **settings):
    A collection of request handlers that make up a web application.
```

Instances of this class are callable and can be passed directly to HTTPServer to serve the application:

```python
application = web.Application([
    (r"/", MainPageHandler),
])
http_server = httpserver.HTTPServer(application)
http_server.listen(8080)
```

The constructor for this class takes in a list of Rule objects or tuples of values corresponding to the arguments of Rule constructor: (matcher, target, [target_kwargs], [name]), the values in square brackets being optional. The default matcher is PathMatches, so (regexp, target) tuples can also be used instead of (PathMatches(regexp), target).

A common routing target is a RequestHandler subclass, but you can also use lists of rules as a target, which create a nested routing configuration:

```python
application = web.Application([
    (HostMatches("example.com"), [
        (r"/", MainPageHandler),
        (r"/feed", FeedHandler),
    ]),
])
```

In addition to this you can use nested Router instances, HTTPMessageDelegate subclasses and callables as routing targets (see routing module docs for more information).
When we receive requests, we iterate over the list in order and instantiate an instance of the first request class whose regexp matches the request path. The request class can be specified as either a class object or a (fully-qualified) name.

A dictionary may be passed as the third element (target_kwargs) of the tuple, which will be used as keyword arguments to the handler’s constructor and initialize method. This pattern is used for the StaticFileHandler in this example (note that a StaticFileHandler can be installed automatically with the static_path setting described below):

```python
application = web.Application([  
    (r"/static/(.*)", web.StaticFileHandler, {"path": "/var/www"}),  
])
```

We support virtual hosts with the add_handlers method, which takes in a host regular expression as the first argument:

```python
application.add_handlers(r"www\.myhost\.com", [  
    (r"/article/([0-9]+)", ArticleHandler),  
])
```

If there’s no match for the current request’s host, then default_host parameter value is matched against host regular expressions.

**Warning:** Applications that do not use TLS may be vulnerable to DNS rebinding attacks. This attack is especially relevant to applications that only listen on 127.0.0.1 or other private networks. Appropriate host patterns must be used (instead of the default of r’.*’) to prevent this risk. The default_host argument must not be used in applications that may be vulnerable to DNS rebinding.

You can serve static files by sending the static_path setting as a keyword argument. We will serve those files from the /static/ URI (this is configurable with the static_url_prefix setting), and we will serve /favicon.ico and /robots.txt from the same directory. A custom subclass of StaticFileHandler can be specified with the static_handler_class setting.

Changed in version 4.5: Integration with the new tornado.routing module.

**settings**

Additional keyword arguments passed to the constructor are saved in the settings dictionary, and are often referred to in documentation as “application settings”. Settings are used to customize various aspects of Tornado (although in some cases richer customization is possible by overriding methods in a subclass of RequestHandler). Some applications also like to use the settings dictionary as a way to make application-specific settings available to handlers without using global variables. Settings used in Tornado are described below.

General settings:

- **autoreload**: If True, the server process will restart when any source files change, as described in *Debug mode and automatic reloading*. This option is new in Tornado 3.2; previously this functionality was controlled by the debug setting.

- **debug**: Shorthand for several debug mode settings, described in *Debug mode and automatic reloading*. Setting debug=True is equivalent to autoreload=True, compiled_template_cache=False, static_hash_cache=False, serve_traceback=True.

- **default_handler_class** and **default_handler_args**: This handler will be used if no other match is found; use this to implement custom 404 pages (new in Tornado 3.2).
• compress_response: If True, responses in textual formats will be compressed automatically. New in Tornado 4.0.

• gzip: Deprecated alias for compress_response since Tornado 4.0.

• log_function: This function will be called at the end of every request to log the result (with one argument, the RequestHandler object). The default implementation writes to the logging module’s root logger. May also be customized by overriding Application.log_request.

• serve_traceback: If True, the default error page will include the traceback of the error. This option is new in Tornado 3.2; previously this functionality was controlled by the debug setting.

• ui_modules and ui_methods: May be set to a mapping of UIModule or UI methods to be made available to templates. May be set to a module, dictionary, or a list of modules and/or dicts. See UI modules for more details.

• websocket_ping_interval: If set to a number, all websockets will be pinged every n seconds. This can help keep the connection alive through certain proxy servers which close idle connections, and it can detect if the websocket has failed without being properly closed.

• websocket_ping_timeout: If the ping interval is set, and the server doesn’t receive a ‘pong’ in this many seconds, it will close the websocket. The default is three times the ping interval, with a minimum of 30 seconds. Ignored if the ping interval is not set.

Authentication and security settings:

• cookie_secret: Used by RequestHandler.get_signed_cookie and set_signed_cookie to sign cookies.

• key_version: Used by requestHandler set_signed_cookie to sign cookies with a specific key when cookie_secret is a key dictionary.

• login_url: The authenticated decorator will redirect to this url if the user is not logged in. Can be further customized by overriding RequestHandler.get_login_url.

• xsrf_cookies: If True, Cross-site request forgery protection will be enabled.

• xsrf_cookie_version: Controls the version of new XSRF cookies produced by this server. Should generally be left at the default (which will always be the highest supported version), but may be set to a lower value temporarily during version transitions. New in Tornado 3.2.2, which introduced XSRF cookie version 2.

• xsrf_cookie_kwags: May be set to a dictionary of additional arguments to be passed to RequestHandler.set_cookie for the XSRF cookie.

• xsrf_cookie_name: Controls the name used for the XSRF cookie (default _xsrf). The intended use is to take advantage of cookie prefixes. Note that cookie prefixes interact with other cookie flags, so they must be combined with xsrf_cookie_kwags, such as {"xsrf_cookie_name": "__Host-xsrf", "xsrf_cookie_kwags": {"secure": True}}

• twitter_consumer_key, twitter_consumer_secret, friendfeed_consumer_key, friendfeed_consumer_secret, google_consumer_key, google_consumer_secret, facebook_api_key, facebook_secret: Used in the tornado.auth module to authenticate to various APIs.

Template settings:

• autoescape: Controls automatic escaping for templates. May be set to None to disable escaping, or to the name of a function that all output should be passed through. Defaults to "xhtml_escape". Can be changed on a per-template basis with the {% autoescape %} directive.
- **compiled_template_cache**: Default is True; if False templates will be recompiled on every request. This option is new in Tornado 3.2; previously this functionality was controlled by the `debug` setting.

- **template_path**: Directory containing template files. Can be further customized by overriding `RequestHandler.get_template_path`.

- **template_loader**: Assign to an instance of `tornado.template.BaseLoader` to customize template loading. If this setting is used the `template_path` and `autoescape` settings are ignored. Can be further customized by overriding `RequestHandler.create_template_loader`.

- **template_whitespace**: Controls handling of whitespace in templates; see `tornado.template.filter_whitespace` for allowed values. New in Tornado 4.3.

Static file settings:

- **static_hash_cache**: Default is True; if False static urls will be recomputed on every request. This option is new in Tornado 3.2; previously this functionality was controlled by the `debug` setting.

- **static_path**: Directory from which static files will be served.

- **static_url_prefix**: Url prefix for static files, defaults to `/static/`.

- **static_handler_class, static_handler_args**: May be set to use a different handler for static files instead of the default `tornado.web.StaticFileHandler`. `static_handler_args`, if set, should be a dictionary of keyword arguments to be passed to the handler’s `initialize` method.

**Application.listen**

```python
Application.listen(port: int, address: Optional[str] = None, *, family: AddressFamily = AddressFamily.AF_UNSPEC, backlog: int = 128, flags: Optional[int] = None, reuse_port: bool = False, **kwargs: Any) → HTTPServer
```

Starts an HTTP server for this application on the given port.

This is a convenience alias for creating an `HTTPServer` object and calling its `listen` method. Keyword arguments not supported by `HTTPServer.listen` are passed to the `HTTPServer` constructor. For advanced uses (e.g. multi-process mode), do not use this method; create an `HTTPServer` and call its `TCPServer.bind/TCPServer.start` methods directly.

Note that after calling this method you still need to call `IOLoop.current().start()` (or run within asyncio.run) to start the server.

Returns the `HTTPServer` object.

Changed in version 4.3: Now returns the `HTTPServer` object.

Changed in version 6.2: Added support for new keyword arguments in `TCPServer.listen`, including `reuse_port`.

**Application.add_handlers**

```python
Application.add_handlers(handlers: List[Union[Rule, Tuple]])
```

Appends the given handlers to our handler list.

Host patterns are processed sequentially in the order they were added. All matching patterns will be considered.

**Application.get_handler_delegate**

```python
Application.get_handler_delegate(request: HTTPServerRequest, target_class: Type[RequestHandler], target_kwargs: Optional[Dict[str, Any]] = None, path_args: Optional[List[bytes]] = None, path_kwargs: Optional[Dict[str, bytes]] = None) → _HandlerDelegate
```

Returns `HTTPMessageDelegate` that can serve a request for application and `RequestHandler` subclass.

**Parameters**

- **request** (`httputil.HTTPServerRequest`) – current HTTP request.

- **target_class** (`RequestHandler`) – a `RequestHandler` class.
• **target_kwargs** (*dict*) – keyword arguments for `target_class` constructor.

• **path_args** (*list*) – positional arguments for `target_class` HTTP method that will be executed while handling a request (`get`, `post` or any other).

• **path_kwargs** (*dict*) – keyword arguments for `target_class` HTTP method.

**Application.reverse_url** *(name: str, *args: Any) → str*

Returns a URL path for handler named `name`

The handler must be added to the application as a named `URLSpec`

Args will be substituted for capturing groups in the `URLSpec` regex. They will be converted to strings if necessary, encoded as utf8, and url-escaped.

**Application.log_request** *(handler: RequestHandler) → None*

Writes a completed HTTP request to the logs.

By default writes to the python root logger. To change this behavior either subclass Application and override this method, or pass a function in the application settings dictionary as `log_function`.

**class** **tornado.web.URLSpec** *(pattern: Union[str, Pattern], handler: Any, kwargs: Optional[Dict[str, Any]] = None, name: Optional[str] = None)*

Specifies mappings between URLs and handlers.

Parameters:

• **pattern**: Regular expression to be matched. Any capturing groups in the regex will be passed in to the handler’s `get/post/etc` methods as arguments (by keyword if named, by position if unnamed. Named and unnamed capturing groups may not be mixed in the same rule).

• **handler**: `RequestHandler` subclass to be invoked.

• **kwargs** (optional): A dictionary of additional arguments to be passed to the handler’s constructor.

• **name** (optional): A name for this handler. Used by `reverse_url`.

The `URLSpec` class is also available under the name `tornado.web.url`.

**Decorators**

**tornado.web.authenticated**(method: Callable[..., Optional[Awaitable[None]]]) → Callable[..., Optional[Awaitable[None]]]

Decorate methods with this to require that the user be logged in.

If the user is not logged in, they will be redirected to the configured `login url`.

If you configure a login url with a query parameter, Tornado will assume you know what you’re doing and use it as-is. If not, it will add a `next` parameter so the login page knows where to send you once you’re logged in.

**tornado.web.addslash**(method: Callable[..., Optional[Awaitable[None]]]) → Callable[..., Optional[Awaitable[None]]]

Use this decorator to add a missing trailing slash to the request path.

For example, a request to `/foo` would redirect to `/foo/` with this decorator. Your request handler mapping should use a regular expression like `r’/foo/?’` in conjunction with using the decorator.

**tornado.web.removeslash**(method: Callable[..., Optional[Awaitable[None]]]) → Callable[..., Optional[Awaitable[None]]]
Use this decorator to remove trailing slashes from the request path.

For example, a request to `/foo/` would redirect to `/foo` with this decorator. Your request handler mapping should use a regular expression like `r'/foo/*'` in conjunction with using the decorator.

```python
from tornado.web import stream_request_body

@stream_request_body
def my_handler(request):
    pass
```

This decorator implies the following changes:

- `HTTPServerRequest.body` is undefined, and body arguments will not be included in `RequestHandler.get_argument`.
- `RequestHandler.prepare` is called when the request headers have been read instead of after the entire body has been read.
- The subclass must define a method `data_received(self, data)`; which will be called zero or more times as data is available. Note that if the request has an empty body, `data_received` may not be called.
- `prepare` and `data_received` may return Futures (such as via `@gen.coroutine`, in which case the next method will not be called until those futures have completed.
- The regular HTTP method (`post`, `put`, etc) will be called after the entire body has been read.

See the file receiver demo for example usage.

### Everything else

**Exception** `tornado.web.HTTPError`

```python
from tornado import web

class MyHandler(web.RequestHandler):
    def get(self):
        raise web.HTTPError(404)
```

An exception that will turn into an HTTP error response.

Raising an `HTTPError` is a convenient alternative to calling `RequestHandler.send_error` since it automatically ends the current function.

To customize the response sent with an `HTTPError`, override `RequestHandler.write_error`.

**Parameters**

- `status_code (int)` – HTTP status code. Must be listed in `httpclient.responses` unless the `reason` keyword argument is given.
- `log_message (str)` – Message to be written to the log for this error (will not be shown to the user unless the `Application` is in debug mode). May contain `%s`-style placeholders, which will be filled in with remaining positional parameters.
- `reason (str)` – Keyword-only argument. The HTTP “reason” phrase to pass in the status line along with `status_code`. Normally determined automatically from `status_code`, but can be used to use a non-standard numeric code.

**Exception** `tornado.web.Finish`

An exception that ends the request without producing an error response.

When `Finish` is raised in a `RequestHandler`, the request will end (calling `RequestHandler.finish` if it hasn’t already been called), but the error-handling methods (including `RequestHandler.write_error`) will not be called.

If `Finish()` was created with no arguments, the pending response will be sent as-is. If `Finish()` was given an argument, that argument will be passed to `RequestHandler.finish()`.
This can be a more convenient way to implement custom error pages than overriding `write_error` (especially in library code):

```python
if self.current_user is None:
    self.set_status(401)
    self.set_header('WWW-Authenticate', 'Basic realm="something"')
    raise Finish()
```

Changed in version 4.3: Arguments passed to `Finish()` will be passed on to `RequestHandler.finish`.

**exception** `tornado.web.MissingArgumentError(arg_name: str)`

Exception raised by `RequestHandler.get_argument`.

This is a subclass of `HTTPError`, so if it is uncaught a 400 response code will be used instead of 500 (and a stack trace will not be logged).

New in version 3.1.

**class** `tornado.web.UIModule(handler: RequestHandler)`

A re-usable, modular UI unit on a page.

UI modules often execute additional queries, and they can include additional CSS and JavaScript that will be included in the output page, which is automatically inserted on page render.

Subclasses of UIModule must override the `render` method.

```python
render(*args: Any, **kwargs: Any) → str
```

Override in subclasses to return this module’s output.

```python
embedded_javascript() → Optional[str]
```

Override to return a JavaScript string to be embedded in the page.

```python
javascript_files() → Optional[Iterable[str]]
```

Override to return a list of JavaScript files needed by this module.

If the return values are relative paths, they will be passed to `RequestHandler.static_url`; otherwise they will be used as-is.

```python
embedded_css() → Optional[str]
```

Override to return a CSS string that will be embedded in the page.

```python
css_files() → Optional[Iterable[str]]
```

Override to return a list of CSS files required by this module.

If the return values are relative paths, they will be passed to `RequestHandler.static_url`; otherwise they will be used as-is.

```python
html_head() → Optional[str]
```

Override to return an HTML string that will be put in the `<head/>` element.

```python
html_body() → Optional[str]
```

Override to return an HTML string that will be put at the end of the `<body/>` element.

```python
render_string(path: str, **kwargs: Any) → bytes
```

Renders a template and returns it as a string.

**class** `tornado.web.ErrorHandler(application: Application, request: HTTPServerRequest, **kwargs: Any)`

Generates an error response with `status_code` for all requests.
class tornado.web.FallbackHandler(application: Application, request: HTTPServerRequest, **kwargs: Any)

A RequestHandler that wraps another HTTP server callback.

The fallback is a callable object that accepts an HTTPServerRequest, such as an Application or tornado.wsgi.WSGIContainer. This is most useful to use both Tornado RequestHandlers and WSGI in the same server. Typical usage:

```python
global wsgi_app = tornado.wsgi.WSGIContainer(django.core.handlers.wsgi.WSGIHandler())
application = tornado.web.Application([ 
    (r"/foo", FooHandler),
    (r".*", FallbackHandler, dict(fallback=wsgi_app)),
])
```

class tornado.web.RedirectHandler(application: Application, request: HTTPServerRequest, **kwargs: Any)

Redirects the client to the given URL for all GET requests.

You should provide the keyword argument url to the handler, e.g.:

```python
application = web.Application([ 
    (r"/oldpath", web.RedirectHandler, {"url": "/newpath"}),
])
```

RedirectHandler supports regular expression substitutions. E.g., to swap the first and second parts of a path while preserving the remainder:

```python
application = web.Application([ 
    (r"/(.*?)/(.*?)/(.*)", web.RedirectHandler, {"url": "/{1}/{0}/{2}"}),
])
```

The final URL is formatted with str.format and the substrings that match the capturing groups. In the above example, a request to "/a/b/c" would be formatted like:

```
str.format("/a/b/c", "a", "b", "c")  # -> "/b/a/c"
```

Use Python's format string syntax to customize how values are substituted.

Changed in version 4.5: Added support for substitutions into the destination URL.

Changed in version 5.0: If any query arguments are present, they will be copied to the destination URL.

class tornado.web.StaticFileHandler(application: Application, request: HTTPServerRequest, **kwargs: Any)

A simple handler that can serve static content from a directory.

A StaticFileHandler is configured automatically if you pass the static_path keyword argument to Application. This handler can be customized with the static_url_prefix, static_handler_class, and static_handler_args settings.

To map an additional path to this handler for a static data directory you would add a line to your application like:

```python
application = web.Application([ 
    (r"/content/(.*)", web.StaticFileHandler, {"path": "/var/www"}),
])
```
The handler constructor requires a `path` argument, which specifies the local root directory of the content to be served.

Note that a capture group in the regex is required to parse the value for the `path` argument to the `get()` method (different than the constructor argument above); see `URLSpec` for details.

To serve a file like `index.html` automatically when a directory is requested, set `static_handler_args=dict(default_filename="index.html")` in your application settings, or add `default_filename` as an initializer argument for your `StaticFileHandler`.

To maximize the effectiveness of browser caching, this class supports versioned urls (by default using the argument `?v=`). If a version is given, we instruct the browser to cache this file indefinitely. `make_static_url` (also available as `RequestHandler.static_url`) can be used to construct a versioned url.

This handler is intended primarily for use in development and light-duty file serving; for heavy traffic it will be more efficient to use a dedicated static file server (such as nginx or Apache). We support the HTTP `Accept-Ranges` mechanism to return partial content (because some browsers require this functionality to be present to seek in HTML5 audio or video).

**Subclassing notes**

This class is designed to be extensible by subclassing, but because of the way static urls are generated with class methods rather than instance methods, the inheritance patterns are somewhat unusual. Be sure to use the `@classmethod` decorator when overriding a class method. Instance methods may use the attributes `self.path`, `self.absolute_path`, and `self.modified`.

Subclasses should only override methods discussed in this section; overriding other methods is error-prone. Overriding `StaticFileHandler.get` is particularly problematic due to the tight coupling with `compute_etag` and other methods.

To change the way static urls are generated (e.g. to match the behavior of another server or CDN), override `make_static_url`, `parse_url_path`, `get_cache_time`, and/or `get_version`.

To replace all interaction with the filesystem (e.g. to serve static content from a database), override `get_content`, `get_content_size`, `get_modified_time`, `get_absolute_path`, and `validate_absolute_path`.

Changed in version 3.1: Many of the methods for subclasses were added in Tornado 3.1.

```python
compute_etag() → Optional[str]

Sets the Etag header based on static url version.

This allows efficient If-None-Match checks against cached versions, and sends the correct Etag for a partial response (i.e. the same Etag as the full file).

New in version 3.1.
```

```python
set_headers() → None

Sets the content and caching headers on the response.

New in version 3.1.
```

```python
should_return_304() → bool

Returns True if the headers indicate that we should return 304.

New in version 3.1.
```

```python
classmethod get_absolute_path(root: str, path: str) → str

Returns the absolute location of `path` relative to `root`.

`root` is the path configured for this `StaticFileHandler` (in most cases the `static_path Application` setting).
```
This class method may be overridden in subclasses. By default it returns a filesystem path, but other strings may be used as long as they are unique and understood by the subclass’s overridden `get_content`.

New in version 3.1.

```python
validate_absolute_path(root: str, absolute_path: str) -> Optional[str]
```

Validate and return the absolute path.

- `root` is the configured path for the `StaticFileHandler`, and `absolute_path` is the result of `get_absolute_path`

This is an instance method called during request processing, so it may raise `HTTPError` or use methods like `RequestHandler.redirect` (return None after redirecting to halt further processing). This is where 404 errors for missing files are generated.

This method may modify the path before returning it, but note that any such modifications will not be understood by `make_static_url`.

In instance methods, this method’s result is available as `self.absolute_path`.

New in version 3.1.

```python
classmethod get_content(abspath: str, start: Optional[int] = None, end: Optional[int] = None) -> Generator[bytes, None, None]
```

Retrieve the content of the requested resource which is located at the given absolute path.

This class method may be overridden by subclasses. Note that its signature is different from other overridable class methods (no `settings` argument); this is deliberate to ensure that `abspath` is able to stand on its own as a cache key.

This method should either return a byte string or an iterator of byte strings. The latter is preferred for large files as it helps reduce memory fragmentation.

New in version 3.1.

```python
classmethod get_content_version(abspath: str) -> str
```

Returns a version string for the resource at the given path.

This class method may be overridden by subclasses. The default implementation is a SHA-512 hash of the file’s contents.

New in version 3.1.

```python
get_content_size() -> int
```

Retrieve the total size of the resource at the given path.

This method may be overridden by subclasses.

New in version 3.1.

Changed in version 4.0: This method is now always called, instead of only when partial results are requested.

```python
get_modified_time() -> Optional[datetime]
```

Returns the time that `self.absolute_path` was last modified.

May be overridden in subclasses. Should return a `datetime` object or None.

New in version 3.1.

Changed in version 6.4: Now returns an aware `datetime` object instead of a naive one. Subclasses that override this method may return either kind.
**get_content_type() → str**

Returns the Content-Type header to be used for this request.

New in version 3.1.

**set_extra_headers(path: str) → None**

For subclass to add extra headers to the response

**get_cache_time(path: str, modified: Optional[datetime], mime_type: str) → int**

Override to customize cache control behavior.

Return a positive number of seconds to make the result cacheable for that amount of time or 0 to mark resource as cacheable for an unspecified amount of time (subject to browser heuristics).

By default returns cache expiry of 10 years for resources requested with v argument.

**classmethod make_static_url(settings: Dict[str, Any], path: str, include_version: bool = True) → str**

Constructs a versioned url for the given path.

This method may be overridden in subclasses (but note that it is a class method rather than an instance method). Subclasses are only required to implement the signature make_static_url(cls, settings, path); other keyword arguments may be passed through static_url but are not standard.

settings is the Application.settings dictionary. path is the static path being requested. The url returned should be relative to the current host.

include_version determines whether the generated URL should include the query string containing the version hash of the file corresponding to the given path.

**parse_url_path(url_path: str) → str**

Converts a static URL path into a filesystem path.

url_path is the path component of the URL with static_url_prefix removed. The return value should be filesystem path relative to static_path.

This is the inverse of make_static_url.

**classmethod get_version(settings: Dict[str, Any], path: str) → Optional[str]**

Generate the version string to be used in static URLs.

settings is the Application.settings dictionary and path is the relative location of the requested asset on the filesystem. The returned value should be a string, or None if no version could be determined.

Changed in version 3.1: This method was previously recommended for subclasses to override; get_content_version is now preferred as it allows the base class to handle caching of the result.

### 6.2.2 tornado.template — Flexible output generation

A simple template system that compiles templates to Python code.

Basic usage looks like:

```python
import tornado.template

t = template.Template("<html>{{ myvalue }}</html>")
print(t.generate(myvalue="XXX"))
```

**Loader** is a class that loads templates from a root directory and caches the compiled templates:

```python
loader = template.Loader("/home/btaylor")
print(loader.load("test.html").generate(myvalue="XXX"))
```
We compile all templates to raw Python. Error-reporting is currently... uh, interesting. Syntax for the templates:

```html
### base.html
<html>
<head>
    <title>{% block title %}Default title{% end %}</title>
</head>
<body>
    <ul>
        {% for student in students %}
            {% block student %}
                <li>{{ escape(student.name) }}</li>
            {% end %}
        {% end %}
    </ul>
</body>
</html>

### bold.html
{% extends "base.html" %}
{% block title %}A bolder title{% end %}
{% block student %}
    <li><span style="bold">{{ escape(student.name) }}</span></li>
{% end %}

Unlike most other template systems, we do not put any restrictions on the expressions you can include in your statements. `if` and `for` blocks get translated exactly into Python, so you can do complex expressions like:

```html
{% for student in [p for p in people if p.student and p.age > 23] %}
    <li>{{ escape(student.name) }}</li>
{% end %}
```

Translating directly to Python means you can apply functions to expressions easily, like the `escape()` function in the examples above. You can pass functions in to your template just like any other variable (In a `RequestHandler`, override `RequestHandler.get_template_namespace`):

```python
### Python code
def add(x, y):
    return x + y
template.execute(add=add)

### The template
{{ add(1, 2) }}
```

We provide the functions `escape()`, `url_escape()`, `json_encode()`, and `squeeze()` to all templates by default.

Typical applications do not create `Template` or `Loader` instances by hand, but instead use the `render` and `render_string` methods of `tornado.web.RequestHandler`, which load templates automatically based on the `template_path` `Application` setting.

Variable names beginning with `_tt_` are reserved by the template system and should not be used by application code.
Syntax Reference

Template expressions are surrounded by double curly braces: `{{ ... }}`. The contents may be any python expression, which will be escaped according to the current autoescape setting and inserted into the output. Other template directives use `{% %}`.

To comment out a section so that it is omitted from the output, surround it with `{# ... #}`.

To include a literal `{, %, or # in the output, escape them as `{!, {%!, and `{#!, respectively.

```{% apply *function* %}...{% end %}
Applies a function to the output of all template code between apply and end:

```
{% apply linkify %}{name} said: {{message}}{% end %}
```

Note that as an implementation detail apply blocks are implemented as nested functions and thus may interact strangely with variables set via `{% set %}`, or the use of `{% break %}` or `{% continue %}` within loops.

```{% autoescape *function* %}
Sets the autoescape mode for the current file. This does not affect other files, even those referenced by `{% include %}`. Note that autoescaping can also be configured globally, at the Application or Loader:

```
{% autoescape xhtml_escape %}
{% autoescape None %}
```

```{% block *name* %}...{% end %}
Indicates a named, replaceable block for use with `{% extends %}`. Blocks in the parent template will be replaced with the contents of the same-named block in a child template:

```<!-- base.html -->
<title>{% block title %}Default title{% end %}</title>

<!-- mypage.html -->
{% extends "base.html" %}
{% block title %}My page title{% end %}
```

```{% comment ... %}
A comment which will be removed from the template output. Note that there is no `{% end %}` tag; the comment goes from the word comment to the closing %} tag.

```{% extends *filename* %}
Inherit from another template. Templates that use extends should contain one or more block tags to replace content from the parent template. Anything in the child template not contained in a block tag will be ignored. For an example, see the `{% block %}` tag.

```{% for *var* in *expr* %}...{% end %}
Same as the python for statement. `{% break %}` and `{% continue %}` may be used inside the loop.

```{% from *x* import *y* %}
Same as the python import statement.

```{% if *condition* %}...{% elif *condition* %}...{% else %}...{% end %}
Conditional statement - outputs the first section whose condition is true. (The else section is optional)

```{% import *module* %}
Same as the python import statement.

```{% include *filename* %}
Includes another template file. The included file can see all the local variables as if it were copied directly to
the point of the include directive (the {% autoescape %} directive is an exception). Alternately, {% module Template(filename, **kwargs) %} may be used to include another template with an isolated namespace.

{% module *expr* %}
Renders a UIModule. The output of the UIModule is not escaped:

{% module Template("foo.html", arg=42) %}

UIModules are a feature of the tornado.web.RequestHandler class (and specifically its render method) and will not work when the template system is used on its own in other contexts.

{% raw *expr* %}
Outputs the result of the given expression without autoescaping.

{% set *x* = *y* %}
Sets a local variable.

{% try %}...{% except %}...{% else %}...{% finally %}...{% end %}
Same as the python try statement.

{% while *condition* %}... {% end %}
Same as the python while statement. {% break %} and {% continue %} may be used inside the loop.

{% whitespace *mode* %}
Sets the whitespace mode for the remainder of the current file (or until the next {% whitespace %} directive).
See filter_whitespace for available options. New in Tornado 4.3.

Class reference

class tornado.template.Template(template_string, name='<string>', loader=None,
    compress_whitespace=None, autoescape='xhtml_escape',
    whitespace=None)

A compiled template.

We compile into Python from the given template_string. You can generate the template from variables with generate().

Construct a Template.

Parameters

- template_string (str) – the contents of the template file.
- name (str) – the filename from which the template was loaded (used for error message).
- loader (tornado.template.BaseLoader) – the BaseLoader responsible for this template, used to resolve {% include %} and {% extend %} directives.
- compress_whitespace (bool) – Deprecated since Tornado 4.3. Equivalent to whitespace="single" if true and whitespace="all" if false.
- autoescape (str) – The name of a function in the template namespace, or None to disable escaping by default.
- whitespace (str) – A string specifying treatment of whitespace; see filter_whitespace for options.

Changed in version 4.3: Added whitespace parameter; deprecated compress_whitespace.

generate(**kwargs: Any) → bytes

Generate this template with the given arguments.
class tornado.template.BaseLoader(autoescape: str = 'xhtml_escape', namespace: Optional[Dict[str, Any]] = None, whitespace: Optional[str] = None)

Base class for template loaders.

You must use a template loader to use template constructs like {% extends %} and {% include %}. The loader caches all templates after they are loaded the first time.

Construct a template loader.

Parameters

- **autoescape** *(str)* – The name of a function in the template namespace, such as “xhtml_escape”, or None to disable autoescaping by default.
- **namespace** *(dict)* – A dictionary to be added to the default template namespace, or None.
- **whitespace** *(str)* – A string specifying default behavior for whitespace in templates; see filter_whitespace for options. Default is “single” for files ending in “.html” and “.js” and “all” for other files.

Changed in version 4.3: Added whitespace parameter.

reset() → None

Resets the cache of compiled templates.

resolve_path(name: str, parent_path: Optional[str] = None) → str

Converts a possibly-relative path to absolute (used internally).

load(name: str, parent_path: Optional[str] = None) → Template

Loads a template.

class tornado.template.Loader(root_directory: str, **kwargs: Any)

A template loader that loads from a single root directory.

class tornado.template.DictLoader(dict: Dict[str, str], **kwargs: Any)

A template loader that loads from a dictionary.

exception tornado.template.ParseError(message: str, filename: Optional[str] = None, lineno: int = 0)

Raised for template syntax errors.

ParseError instances have filename and lineno attributes indicating the position of the error.

Changed in version 4.3: Added filename and lineno attributes.

tornado.template.filter_whitespace(mode: str, text: str) → str

Transform whitespace in text according to mode.

Available modes are:

- **all**: Return all whitespace unmodified.
- **single**: Collapse consecutive whitespace with a single whitespace character, preserving newlines.
- **oneline**: Collapse all runs of whitespace into a single space character, removing all newlines in the process.

New in version 4.3.
6.2.3 tornado.routing — Basic routing implementation

Flexible routing implementation.

Tornado routes HTTP requests to appropriate handlers using Router class implementations. The tornado.web.Application class is a Router implementation and may be used directly, or the classes in this module may be used for additional flexibility. The RuleRouter class can match on more criteria than Application, or the Router interface can be subclassed for maximum customization.

Router interface extends HTTPServerConnectionDelegate to provide additional routing capabilities. This also means that any Router implementation can be used directly as a request_callback for HTTPServer constructor.

Router subclass must implement a find_handler method to provide a suitable HTTPMessageDelegate instance to handle the request:

```python
class CustomRouter(Router):
    def find_handler(self, request, **kwargs):
        # some routing logic providing a suitable HTTPMessageDelegate instance
        return MessageDelegate(request.connection)

class MessageDelegate(HTTPMessageDelegate):
    def __init__(self, connection):
        self.connection = connection

    def finish(self):
        self.connection.write_headers(
            ResponseStartLine("HTTP/1.1", 200, "OK"),
            HTTPHeaders({"Content-Length": "2"}),
            b"OK"
        )
        self.connection.finish()

router = CustomRouter()
server = HTTPServer(router)
```

The main responsibility of Router implementation is to provide a mapping from a request to HTTPMessageDelegate instance that will handle this request. In the example above we can see that routing is possible even without instantiating an Application.

For routing to RequestHandler implementations we need an Application instance. get_handler_delegate provides a convenient way to create HTTPMessageDelegate for a given request and RequestHandler.

Here is a simple example of how we can route to RequestHandler subclasses by HTTP method:

```python
resources = {}

class GetResource(RequestHandler):
    def get(self, path):
        if path not in resources:
            raise HTTPError(404)
        self.finish(resources[path])

class PostResource(RequestHandler):
    def post(self, path):
        resources[path] = self.request.body

(continues on next page)
class HTTPMethodRouter(Router):
    def __init__(self, app):
        self.app = app

    def find_handler(self, request, **kwargs):
        handler = GetResource if request.method == "GET" else PostResource
        return self.app.get_handler_delegate(request, handler, path_args=[request.path])

router = HTTPMethodRouter(Application())
server = HTTPServer(router)

ReversibleRouter interface adds the ability to distinguish between the routes and reverse them to the original urls using route's name and additional arguments. Application is itself an implementation of ReversibleRouter class.

RuleRouter and ReversibleRuleRouter are implementations of Router and ReversibleRouter interfaces and can be used for creating rule-based routing configurations.

Rules are instances of Rule class. They contain a Matcher, which provides the logic for determining whether the rule is a match for a particular request and a target, which can be one of the following.

1) An instance of HTTPServerConnectionDelegate:

    router = RuleRouter([
        Rule(PathMatches("/handler"), ConnectionDelegate()),
        # ... more rules
    ])

    class ConnectionDelegate(HTTPServerConnectionDelegate):
        def start_request(self, server_conn, request_conn):
            return MessageDelegate(request_conn)

2) A callable accepting a single argument of HTTPServerRequest type:

    router = RuleRouter([
        Rule(PathMatches("/callable"), request_callable)
    ])

    def request_callable(request):
        request.write(b"HTTP/1.1 200 OK\r\n\nContent-Length: 2\r\n\n\nOK")
        request.finish()

3) Another Router instance:

    router = RuleRouter([
        Rule(PathMatches("/router.*"), CustomRouter())
    ])

Of course a nested RuleRouter or a Application is allowed:

    router = RuleRouter([
        Rule(HostMatches("example.com"), RuleRouter([
            Rule(PathMatches("/app1/.*") Application(["/app1/handler", Handler]])),
        ]))
    ])

(continues on next page)
server = HTTPServer(router)

In the example below RuleRouter is used to route between applications:

```python
app1 = Application([
    (r"/app1/handler", Handler1),
    # other handlers ...
])

app2 = Application([
    (r"/app2/handler", Handler2),
    # other handlers ...
])

router = RuleRouter([
    Rule(PathMatches("/app1.*"), app1),
    Rule(PathMatches("/app2.*"), app2)
])

server = HTTPServer(router)
```

For more information on application-level routing see docs for Application.

New in version 4.5.

```python
class tornado.routing.Router

Abstract router interface.

find_handler(request: HTTPServerRequest, **kwargs: Any) → Optional[HTTPMessageDelegate]

Must be implemented to return an appropriate instance of HTTPMessageDelegate that can serve the request. Routing implementations may pass additional kwargs to extend the routing logic.

Parameters

• request (httputil.HTTPServerRequest) – current HTTP request.
• kwargs – additional keyword arguments passed by routing implementation.

Returns

an instance of HTTPMessageDelegate that will be used to process the request.

class tornado.routing.ReversibleRouter

Abstract router interface for routers that can handle named routes and support reversing them to original urls.

reverse_url(name: str, *args: Any) → Optional[str]

Returns url string for a given route name and arguments or None if no match is found.

Parameters

• name (str) – route name.
• args – url parameters.

Returns

parametrized url string for a given route name (or None).
```
class tornado.routing.RuleRouter:

Rule-based router implementation.
Constructs a router from an ordered list of rules:

```python
RuleRouter([  
    Rule(PathMatches("/handler"), Target),  
    # ... more rules
])
```

You can also omit explicit Rule constructor and use tuples of arguments:

```python
RuleRouter([  
    (PathMatches("/handler"), Target),
])
```

`PathMatches` is a default matcher, so the example above can be simplified:

```python
RuleRouter([  
    ("/handler", Target),
])
```

In the examples above, Target can be a nested Router instance, an instance of `HTTPServerConnectionDelegate` or an old-style callable, accepting a request argument.

**Parameters**
- `rules` – a list of Rule instances or tuples of Rule constructor arguments.

**add_rules**

```python
add_rules(rules: List[Union[Rule, List[Any], Tuple[Union[str, Matcher], Any, Dict[str, Any]], Tuple[Union[str, Matcher], Any, Dict[str, Any], str]]]) → None
```

Appends new rules to the router.

**Parameters**
- `rules` – a list of Rule instances (or tuples of arguments, which are passed to Rule constructor).

**process_rule**

```python
process_rule(rule: Rule) → Rule
```

Override this method for additional preprocessing of each rule.

**Parameters**
- `rule` (Rule) – a rule to be processed.

**Returns**
the same or modified Rule instance.

**get_target_delegate**

```python
get_target_delegate(target: Any, request: HTTPServerRequest, **target_params: Any) → Optional[HTTPMessageDelegate]
```

Returns an instance of `HTTPMessageDelegate` for a Rule’s target. This method is called by `find_handler` and can be extended to provide additional target types.

**Parameters**
- `target` – a Rule’s target.
- `request` (httputil.HTTPServerRequest) – current request.
- `target_params` – additional parameters that can be useful for `HTTPMessageDelegate` creation.
class tornado.routing.ReversibleRuleRouter:

A rule-based router that implements reverse_url method.

Each rule added to this router may have a name attribute that can be used to reconstruct an original uri. The actual reconstruction takes place in a rule’s matcher (see Matcher.reverse).

class tornado.routing.Rule:

A routing rule.

Constructs a Rule instance.

Parameters

- matcher (Matcher) – a Matcher instance used for determining whether the rule should be considered a match for a specific request.
- target – a Rule’s target (typically a RequestHandler or HTTPServerConnectionDelegate subclass or even a nested Router, depending on routing implementation).
- target_kwargs (dict) – a dict of parameters that can be useful at the moment of target instantiation (for example, status_code for a RequestHandler subclass). They end up in target_params['target_kwargs'] of RuleRouter.get_target_delegate method.
- name (str) – the name of the rule that can be used to find it in ReversibleRouter.reverse_url implementation.

class tornado.routing.Matcher:

Represents a matcher for request features.

match(request: HTTPServerRequest) → Optional[Dict[str, Any]]

Matches current instance against the request.

Parameters

request (httputil.HTTPServerRequest) – current HTTP request

Returns

a dict of parameters to be passed to the target handler (for example, handler_kwargs, path_args, path_kwars can be passed for proper RequestHandler instantiation). An empty dict is a valid (and common) return value to indicate a match when the argument-passing features are not used. None must be returned to indicate that there is no match.

reverse(*args: Any) → Optional[str]

Reconstructs full url from matcher instance and additional arguments.

class tornado.routing.AnyMatches:

Matches any request.

class tornado.routing.HostMatches:

Matches requests from hosts specified by host_pattern regex.

class tornado.routing_DefaultHostMatches:

Matches requests from host that is equal to application’s default_host. Always returns no match if X-Real-Ip header is present.
class tornado.routing.PathMatches(path_pattern: Union[str, Pattern])

Matches requests with paths specified by path_pattern regex.

class tornado.routing.URLSpec(pattern: Union[str, Pattern], handler: Any, kwargs: Optional[Dict[str, Any]] = None, name: Optional[str] = None)

Specifies mappings between URLs and handlers.

Parameters:

- **pattern**: Regular expression to be matched. Any capturing groups in the regex will be passed in to the handler’s get/post/etc methods as arguments (by keyword if named, by position if unnamed. Named and unnamed capturing groups may not be mixed in the same rule).
- **handler**: RequestHandler subclass to be invoked.
- **kwargs** (optional): A dictionary of additional arguments to be passed to the handler’s constructor.
- **name** (optional): A name for this handler. Used by reverse_url.

### 6.2.4 tornado.escape — Escaping and string manipulation

Escaping/unescaping methods for HTML, JSON, URLs, and others.

Also includes a few other miscellaneous string manipulation functions that have crept in over time.

#### Escaping functions

**tornado.escape.xhtml_escape**(value: Union[str, bytes]) → str

Escapes a string so it is valid within HTML or XML.

Escapes the characters <, >, ", '`, and &. When used in attribute values the escaped strings must be enclosed in quotes.

Changed in version 3.2: Added the single quote to the list of escaped characters.

**tornado.escape.xhtml_unescape**(value: Union[str, bytes]) → str

Un-escapes an XML-escaped string.

**tornado.escape.url_escape**(value: Union[str, bytes], plus: bool = True) → str

Returns a URL-encoded version of the given value.

If plus is true (the default), spaces will be represented as “+” instead of “%20”. This is appropriate for query strings but not for the path component of a URL. Note that this default is the reverse of Python’s urllib module.

New in version 3.1: The plus argument

**tornado.escape.url_unescape**(value: Union[str, bytes], encoding: None, plus: bool = True) → bytes

**tornado.escape.url_unescape**(value: Union[str, bytes], encoding: str = 'utf-8', plus: bool = True) → str

Decodes the given value from a URL.

The argument may be either a byte or unicode string.

If encoding is None, the result will be a byte string. Otherwise, the result is a unicode string in the specified encoding.

If plus is true (the default), plus signs will be interpreted as spaces (literal plus signs must be represented as “%2B”). This is appropriate for query strings and form-encoded values but not for the path component of a URL. Note that this default is the reverse of Python’s urllib module.

New in version 3.1: The plus argument
tornado.escape.json_encode(value: Any) → str

JSON-encodes the given Python object.

tornado.escape.json_decode(value: Union[str, bytes]) → Any

Returns Python objects for the given JSON string.

Supports both str and bytes inputs.

**Byte/unicode conversions**

tornado.escape.utf8(value: bytes) → bytes

tornado.escape.utf8(value: str) → bytes

tornado.escape.utf8(value: None) → None

Converts a string argument to a byte string.

If the argument is already a byte string or None, it is returned unchanged. Otherwise it must be a unicode string and is encoded as utf8.

tornado.escape.to_unicode(value: str) → str

tornado.escape.to_unicode(value: bytes) → str

tornado.escape.to_unicode(value: None) → None

Converts a string argument to a unicode string.

If the argument is already a unicode string or None, it is returned unchanged. Otherwise it must be a byte string and is decoded as utf8.

tornado.escape.native_str()

tornado.escape.to_basestring()

Converts a byte or unicode string into type str. These functions were used to help transition from Python 2 to Python 3 but are now deprecated aliases for to_unicode.

tornado.escape.recursive_unicode(obj: Any) → Any

Walks a simple data structure, converting byte strings to unicode.

Supports lists, tuples, and dictionaries.

**Miscellaneous functions**

Converts plain text into HTML with links.

Parameters:

- shorten: Long urls will be shortened for display.
- extra_params: Extra text to include in the link tag, or a callable taking the link as an argument and returning the extra text e.g. linkify(text, extra_params='rel="nofollow" class="external"'), or:
def extra_params_cb(url):
    if url.startswith("http://example.com"):
        return 'class="internal"
    else:
        return 'class="external" rel="nofollow"
linkify(text, extra_params=extra_params_cb)

• require_protocol: Only linkify urls which include a protocol. If this is False, urls such as www.facebook.com will also be linkified.

• permitted_protocols: List (or set) of protocols which should be linkified, e.g. linkify(text, permitted_protocols=["http", "ftp", "mailto"]). It is very unsafe to include protocols such as javascript.

tornado.escape.squeeze(value: str) → str
Replace all sequences of whitespace chars with a single space.

6.2.5 tornado.locale — Internationalization support

Translation methods for generating localized strings.

To load a locale and generate a translated string:

```python
user_locale = tornado.locale.get("es_LA")
print(user_locale.translate("Sign out"))
```

tornado.locale.get() returns the closest matching locale, not necessarily the specific locale you requested. You can support pluralization with additional arguments to translate(), e.g.:

```python
people = [...]
message = user_locale.translate(
    "%(list)s is online", "%(list)s are online", len(people))
print(message % {"list": user_locale.list(people)})
```

The first string is chosen if len(people) == 1, otherwise the second string is chosen.

Applications should call one of load_translations (which uses a simple CSV format) or load_gettext_translations (which uses the .mo format supported by gettext and related tools). If neither method is called, the Locale.translate method will simply return the original string.

tornado.locale.get(*locale_codes: str) → Locale
Retorna the closest match for the given locale codes.

We iterate over all given locale codes in order. If we have a tight or a loose match for the code (e.g., “en” for “en_US”), we return the locale. Otherwise we move to the next code in the list.

By default we return en_US if no translations are found for any of the specified locales. You can change the default locale with set_default_locale().

tornado.locale.set_default_locale(code: str) → None
Sets the default locale.

The default locale is assumed to be the language used for all strings in the system. The translations loaded from disk are mappings from the default locale to the destination locale. Consequently, you don’t need to create a translation file for the default locale.
tornado.locale.load_translations(directory: str, encoding: Optional[str] = None) → None

Loads translations from CSV files in a directory.

Translations are strings with optional Python-style named placeholders (e.g., My name is %(name)s) and their associated translations.

The directory should have translation files of the form LOCALE.csv, e.g. es_GT.csv. The CSV files should have two or three columns: string, translation, and an optional plural indicator. Plural indicators should be one of “plural” or “singular”. A given string can have both singular and plural forms. For example %(name)s liked this may have a different verb conjugation depending on whether %(name)s is one name or a list of names. There should be two rows in the CSV file for that string, one with plural indicator “singular”, and one “plural”. For strings with no verbs that would change on translation, simply use “unknown” or the empty string (or don’t include the column at all).

The file is read using the csv module in the default “excel” dialect. In this format there should not be spaces after the commas.

If no encoding parameter is given, the encoding will be detected automatically (among UTF-8 and UTF-16) if the file contains a byte-order marker (BOM), defaulting to UTF-8 if no BOM is present.

Example translation es_LA.csv:

<table>
<thead>
<tr>
<th>I love you</th>
<th>Te amo</th>
</tr>
</thead>
<tbody>
<tr>
<td>%(name)s liked this</td>
<td>A %(name)s le gustó esto</td>
</tr>
<tr>
<td>%(name)s liked this</td>
<td>A %(name)s le gustó esto</td>
</tr>
</tbody>
</table>

Changed in version 4.3: Added encoding parameter. Added support for BOM-based encoding detection, UTF-16, and UTF-8-with-BOM.

tornado.locale.load_gettext_translations(directory: str, domain: str) → None

Loads translations from gettext’s locale tree

Locale tree is similar to system’s /usr/share/locale, like:

{directory}/{lang}/LC_MESSAGES/{domain}.mo

Three steps are required to have your app translated:

1. Generate POT translation file:
   
   ```
   xgettext --language=Python --keyword=_:1,2 -d mydomain file1.py file2.html etc
   ```

2. Merge against existing POT file:
   
   ```
   msgmerge old.po mydomain.po > new.po
   ```

3. Compile:
   
   ```
   msgfmt mydomain.po -o {directory}/pt_BR/LC_MESSAGES/mydomain.mo
   ```

tornado.locale.get_supported_locales() → Iterable[str]

Returns a list of all the supported locale codes.

class tornado.locale.Locale(code: str)

Object representing a locale.

After calling one of load_translations or load_gettext_translations, call get or get_closest to get a Locale object.
classmethod get_closest(*locale_codes: str) → Locale
Returns the closest match for the given locale code.

classmethod get(code: str) → Locale
Returns the Locale for the given locale code.

If it is not supported, we raise an exception.

translate(message: str, plural_message: Optional[str] = None, count: Optional[int] = None) → str
Returns the translation for the given message for this locale.

If plural_message is given, you must also provide count. We return plural_message when count != 1, and we return the singular form for the given message when count == 1.

format_date(date: Union[int, float, datetime], gmt_offset: int = 0, relative: bool = True, shorter: bool = False, full_format: bool = False) → str
Formats the given date.

By default, we return a relative time (e.g., “2 minutes ago”). You can return an absolute date string with relative=False.

You can force a full format date (“July 10, 1980”) with full_format=True.

This method is primarily intended for dates in the past. For dates in the future, we fall back to full format.

Changed in version 6.4: Aware datetime.datetime objects are now supported (naive datetimes are still assumed to be UTC).

format_day(date: datetime, gmt_offset: int = 0, dow: bool = True) → bool
Formats the given date as a day of week.

Example: “Monday, January 22”. You can remove the day of week with dow=False.

list(parts: Any) → str
Returns a comma-separated list for the given list of parts.

The format is, e.g., “A, B and C”, “A and B” or just “A” for lists of size 1.

friendly_number(value: int) → str
Returns a comma-separated number for the given integer.

class tornado.locale.CSVLocale(code: str, translations: Dict[str, Dict[str, str]])
Locale implementation using tornado’s CSV translation format.

class tornado.locale.GettextLocale(code: str, translations: NullTranslations)
Locale implementation using the gettext module.

pgettext(context: str, message: str, plural_message: Optional[str] = None, count: Optional[int] = None) → str
Allows to set context for translation, accepts plural forms.

Usage example:

```python
pgettext("law", "right")
pgettext("good", "right")
```

Plural message example:

```python
pgettext("organization", "club", "clubs", len(clubs))
pgettext("stick", "club", "clubs", len(clubs))
```
To generate POT file with context, add following options to step 1 of \texttt{load\_gettext\_translations} sequence:

\begin{verbatim}
xgettext [basic options] --keyword=pgettext:1c,2 --keyword=pgettext:1c,2,3
\end{verbatim}

New in version 4.2.

\section*{6.2.6 \texttt{tornado.websocket} — Bidirectional communication to the browser}

Implementation of the WebSocket protocol.

WebSockets allow for bidirectional communication between the browser and server. WebSockets are supported in the current versions of all major browsers.

This module implements the final version of the WebSocket protocol as defined in RFC 6455.

Changed in version 4.0: Removed support for the draft 76 protocol version.

\begin{verbatim}
class tornado.websocket.WebSocketHandler (application: Application, request: HTTPServerRequest, **kwargs: Any)
\end{verbatim}

Subclass this class to create a basic WebSocket handler.

Override \texttt{on\_message} to handle incoming messages, and use \texttt{write\_message} to send messages to the client. You can also override \texttt{open} and \texttt{on\_close} to handle opened and closed connections.

Custom upgrade response headers can be sent by overriding \texttt{set\_default\_headers} or \texttt{prepare}.

See \url{http://dev.w3.org/html5/websockets/} for details on the JavaScript interface. The protocol is specified at \url{http://tools.ietf.org/html/rfc6455}.

Here is an example WebSocket handler that echos back all received messages back to the client:

\begin{verbatim}
class EchoWebSocket (tornado.websocket.WebSocketHandler):
    def open(self):
        print("WebSocket opened")
    def on_message(self, message):
        self.write_message(u"You said: " + message)
    def on_close(self):
        print("WebSocket closed")
\end{verbatim}

WebSockets are not standard HTTP connections. The “handshake” is HTTP, but after the handshake, the protocol is message-based. Consequently, most of the Tornado HTTP facilities are not available in handlers of this type. The only communication methods available to you are \texttt{write\_message()}, \texttt{ping()}, and \texttt{close()}. Likewise, your request handler class should implement \texttt{open()} method rather than \texttt{get()} or \texttt{post()}.

If you map the handler above to /websocket in your application, you can invoke it in JavaScript with:

\begin{verbatim}
var ws = new WebSocket("ws://localhost:8888/websocket");
ws.onopen = function() {
    ws.send("Hello, world");
};
ws.onmessage = function (evt) {
    alert(evt.data);
};
\end{verbatim}
This script pops up an alert box that says “You said: Hello, world”.

Web browsers allow any site to open a websocket connection to any other, instead of using the same-origin policy that governs other network access from JavaScript. This can be surprising and is a potential security hole, so since Tornado 4.0 WebSocketHandler requires applications that wish to receive cross-origin websockets to opt in by overriding the check_origin method (see that method’s docs for details). Failure to do so is the most likely cause of 403 errors when making a websocket connection.

When using a secure websocket connection (wss://) with a self-signed certificate, the connection from a browser may fail because it wants to show the “accept this certificate” dialog but has nowhere to show it. You must first visit a regular HTML page using the same certificate to accept it before the websocket connection will succeed.

If the application setting websocket_ping_interval has a non-zero value, a ping will be sent periodically, and the connection will be closed if a response is not received before the websocket_ping_timeout.

Messages larger than the websocket_max_message_size application setting (default 10MiB) will not be accepted.

Changed in version 4.5: Added websocket_ping_interval, websocket_ping_timeout, and websocket_max_message_size.

**Event handlers**

WebSocketHandler.open(*args: str, **kwargs: str) → Optional[Awaitable[None]]

Invoked when a new WebSocket is opened.

The arguments to open are extracted from the tornado.web.URLSpec regular expression, just like the arguments to tornado.web.RequestHandler.get.

open may be a coroutine. on_message will not be called until open has returned.

Changed in version 5.1: open may be a coroutine.

WebSocketHandler.on_message(message: Union[str, bytes]) → Optional[Awaitable[None]]

Handle incoming messages on the WebSocket

This method must be overridden.

Changed in version 4.5: on_message can be a coroutine.

WebSocketHandler.on_close() → None

Invoked when the WebSocket is closed.

If the connection was closed cleanly and a status code or reason phrase was supplied, these values will be available as the attributes self.close_code and self.close_reason.

Changed in version 4.0: Added close_code and close_reason attributes.

WebSocketHandler.select_subprotocol(subprotocols: List[str]) → Optional[str]

Override to implement subprotocol negotiation.

subprotocols is a list of strings identifying the subprotocols proposed by the client. This method may be overridden to return one of those strings to select it, or None to not select a subprotocol.

Failure to select a subprotocol does not automatically abort the connection, although clients may close the connection if none of their proposed subprotocols was selected.

The list may be empty, in which case this method must return None. This method is always called exactly once even if no subprotocols were proposed so that the handler can be advised of this fact.
Changed in version 5.1: Previously, this method was called with a list containing an empty string instead of an empty list if no subprotocols were proposed by the client.

**WebSocketHandler.**

### selected_subprotocol

The subprotocol returned by `select_subprotocol`.

New in version 5.1.

### on_ping(data: bytes) → None

Invoked when the a ping frame is received.

**Output**

**WebSocketHandler.**

### write_message(message: Union[bytes, str, Dict[str, Any]], binary: bool = False) → Future[None]

Sends the given message to the client of this Web Socket.

The message may be either a string or a dict (which will be encoded as json). If the `binary` argument is false, the message will be sent as utf8; in binary mode any byte string is allowed.

If the connection is already closed, raises `WebSocketClosedError`. Returns a `Future` which can be used for flow control.

Changed in version 3.2: `WebSocketClosedError` was added (previously a closed connection would raise an `AttributeError`)

Changed in version 4.3: Returns a `Future` which can be used for flow control.

Changed in version 5.0: Consistently raises `WebSocketClosedError`. Previously could sometimes raise `StreamClosedError`.

### close(code: Optional[int] = None, reason: Optional[str] = None) → None

Closes this Web Socket.

Once the close handshake is successful the socket will be closed.

`code` may be a numeric status code, taken from the values defined in RFC 6455 section 7.4.1. `reason` may be a textual message about why the connection is closing. These values are made available to the client, but are not otherwise interpreted by the websocket protocol.

Changed in version 4.0: Added the `code` and `reason` arguments.

**Configuration**

### check_origin(origin: str) → bool

Override to enable support for allowing alternate origins.

The `origin` argument is the value of the Origin HTTP header, the url responsible for initiating this request. This method is not called for clients that do not send this header; such requests are always allowed (because all browsers that implement WebSockets support this header, and non-browser clients do not have the same cross-site security concerns).

Should return `True` to accept the request or `False` to reject it. By default, rejects all requests with an origin on a host other than this one.

This is a security protection against cross site scripting attacks on browsers, since WebSockets are allowed to bypass the usual same-origin policies and don’t use CORS headers.
Warning: This is an important security measure; don’t disable it without understanding the security implications. In particular, if your authentication is cookie-based, you must either restrict the origins allowed by `check_origin()` or implement your own XSRF-like protection for websocket connections. See these articles for more.

To accept all cross-origin traffic (which was the default prior to Tornado 4.0), simply override this method to always return `True`:

```python
def check_origin(self, origin):
    return True
```

To allow connections from any subdomain of your site, you might do something like:

```python
def check_origin(self, origin):
    parsed_origin = urllib.parse.urlparse(origin)
    return parsed_origin.netloc.endswith(".mydomain.com")
```

New in version 4.0.

WebSocketHandler.get_compression_options() → Optional[Dict[str, Any]]

Override to return compression options for the connection.

If this method returns `None` (the default), compression will be disabled. If it returns a dict (even an empty one), it will be enabled. The contents of the dict may be used to control the following compression options:

- `compression_level` specifies the compression level.
- `mem_level` specifies the amount of memory used for the internal compression state.

These parameters are documented in details here: [https://docs.python.org/3.6/library/zlib.html#zlib.compressobj](https://docs.python.org/3.6/library/zlib.html#zlib.compressobj)

New in version 4.1.

Changed in version 4.5: Added `compression_level` and `mem_level`.

WebSocketHandler.set_nodelay(value: bool) → None

Set the no-delay flag for this stream.

By default, small messages may be delayed and/or combined to minimize the number of packets sent. This can sometimes cause 200-500ms delays due to the interaction between Nagle’s algorithm and TCP delayed ACKs. To reduce this delay (at the expense of possibly increasing bandwidth usage), call `self.set_nodelay(True)` once the websocket connection is established.

See `BaseIOStream.set_nodelay` for additional details.

New in version 3.1.
Other

WebSocketHandler.ping(data: Union[str, bytes] = b'') → None

Send ping frame to the remote end.

The data argument allows a small amount of data (up to 125 bytes) to be sent as a part of the ping message. Note that not all websocket implementations expose this data to applications.

Consider using the websocket_ping_interval application setting instead of sending pings manually.

Changed in version 5.1: The data argument is now optional.

WebSocketHandler.on_pong(data: bytes) → None

Invoked when the response to a ping frame is received.

exception tornado.websocket.WebSocketClosedError

Raised by operations on a closed connection.

New in version 3.2.

Client-side support

tornado.websocket.websocket_connect(url: Union[str, HTTPRequest], callback:
    Optional[Callable[[Future[WebSocketClientConnection]], None]] = None,
    connect_timeout: Optional[float] = None,
    on_message_callback: Optional[Callable[[Union[None, str, bytes]], None]] = None,
    compression_options: Optional[Dict[str, Any]] = None,
    ping_interval: Optional[float] = None,
    ping_timeout: Optional[float] = None,
    max_message_size: int = 10485760,
    subprotocols: Optional[List[str]] = None,
    resolver: Optional[Resolver] = None) →
    Awaitable[WebSocketClientConnection]

Client-side websocket support.

Takes a url and returns a Future whose result is a WebSocketClientConnection.

compression_options is interpreted in the same way as the return value of WebSocketHandler.get_compression_options.

The connection supports two styles of operation. In the coroutine style, the application typically calls read_message in a loop:

```python
conn = yield websocket_connect(url)
while True:
    msg = yield conn.read_message()
    if msg is None: break
    # Do something with msg
```

In the callback style, pass an on_message_callback to websocket_connect. In both styles, a message of None indicates that the connection has been closed.

subprotocols may be a list of strings specifying proposed subprotocols. The selected protocol may be found on the selected_subprotocol attribute of the connection object when the connection is complete.

Changed in version 3.2: Also accepts HTTPRequest objects in place of urls.

Changed in version 4.1: Added compression_options and on_message_callback.
Changed in version 4.5: Added the ping_interval, ping_timeout, and max_message_size arguments, which have the same meaning as in WebSocketHandler.

Changed in version 5.0: The io_loop argument (deprecated since version 4.1) has been removed.

Changed in version 5.1: Added the subprotocols argument.

Changed in version 6.3: Added the resolver argument.

WebSocket client connection.

This class should not be instantiated directly; use the websocket_connect function instead.

close(code: Optional[int] = None, reason: Optional[str] = None) -> None

Closes the websocket connection.

code and reason are documented under WebSocketHandler.close.

New in version 3.2.

Changed in version 4.0: Added the code and reason arguments.

write_message(message: Union[str, bytes, Dict[str, Any]], binary: bool = False) -> Future[None]

Sends a message to the WebSocket server.

If the stream is closed, raises WebSocketClosedError. Returns a Future which can be used for flow control.

Changed in version 5.0: Exception raised on a closed stream changed from StreamClosedError to WebSocketClosedError.

read_message(callback: Optional[Callable[[Future[Union[None, str, bytes]]], None]] = None) ->Awaitable[Union[None, str, bytes]]

Reads a message from the WebSocket server.

If on_message_callback was specified at WebSocket initialization, this function will never return messages.

Returns a future whose result is the message, or None if the connection is closed. If a callback argument is given it will be called with the future when it is ready.

ping(data: bytes = b") -> None

Send ping frame to the remote end.

The data argument allows a small amount of data (up to 125 bytes) to be sent as a part of the ping message. Note that not all websocket implementations expose this data to applications.

Consider using the ping_interval argument to websocket_connect instead of sending pings manually.

New in version 5.1.

property selected_subprotocol: Optional[str]

The subprotocol selected by the server.

New in version 5.1.
6.3 HTTP servers and clients

6.3.1 tornado.httpserver — Non-blocking HTTP server

A non-blocking, single-threaded HTTP server.

Typical applications have little direct interaction with the HTTPServer class except to start a server at the beginning of the process (and even that is often done indirectly via tornado.web.Application.listen).

Changed in version 4.0: The HTTPRequest class that used to live in this module has been moved to tornado.httputil.HTTPServerRequest. The old name remains as an alias.

HTTP Server

A non-blocking, single-threaded HTTP server.

A server is defined by a subclass of HTTPServerConnectionDelegate, or, for backwards compatibility, a callback that takes an HTTPServerRequest as an argument. The delegate is usually a tornado.web.Application.

HTTPServer supports keep-alive connections by default (automatically for HTTP/1.1, or for HTTP/1.0 when the client requests Connection: keep-alive).

If xheaders is True, we support the X-Real-Ip/X-Forwarded-For and X-Scheme/X-Forwarded-Proto headers, which override the remote IP and URI scheme/protocol for all requests. These headers are useful when running Tornado behind a reverse proxy or load balancer. The protocol argument can also be set to https if Tornado is run behind an SSL-decoding proxy that does not set one of the supported xheaders.

By default, when parsing the X-Forwarded-For header, Tornado will select the last (i.e., the closest) address on the list of hosts as the remote host IP address. To select the next server in the chain, a list of trusted downstream hosts may be passed as the trusted_downstream argument. These hosts will be skipped when parsing the X-Forwarded-For header.

To make this server serve SSL traffic, send the ssl_options keyword argument with an ssl.SSLContext object. For compatibility with older versions of Python ssl_options may also be a dictionary of keyword arguments for the ssl.wrap_socket method:

```python
ssl_ctx = ssl.create_default_context(ssl.Purpose.CLIENT_AUTH)
ssl_ctx.load_cert_chain(os.path.join(data_dir, "mydomain.crt"), os.path.join(data_dir, "mydomain.key"))
HTTPServer(application, ssl_options=ssl_ctx)
```

HTTPServer initialization follows one of three patterns (the initialization methods are defined on tornado.tcpserver.TCPServer):

1. listen: single-process:
async def main():
    server = HTTPServer()
    server.listen(8888)
    await asyncio.Event().wait()

asyncio.run(main())

In many cases, `tornado.web.Application.listen` can be used to avoid the need to explicitly create the `HTTPServer`.

While this example does not create multiple processes on its own, when the `reuse_port=True` argument is passed to `listen()` you can run the program multiple times to create a multi-process service.

2. **add_sockets**: multi-process:

```python
sockets = bind_sockets(8888)
tornado.process.fork_processes(0)
async def post_fork_main():
    server = HTTPServer()
    server.add_sockets(sockets)
    await asyncio.Event().wait()
asyncio.run(post_fork_main())
```

The `add_sockets` interface is more complicated, but it can be used with `tornado.process.fork_processes` to run a multi-process service with all worker processes forked from a single parent. `add_sockets` can also be used in single-process servers if you want to create your listening sockets in some way other than `bind_sockets`.

Note that when using this pattern, nothing that touches the event loop can be run before `fork_processes`.

3. **bind/start**: simple deprecated multi-process:

```python
server = HTTPServer()
server.bind(8888)
server.start(0)  # Forks multiple sub-processes
IOLoop.current().start()
```

This pattern is deprecated because it requires interfaces in the `asyncio` module that have been deprecated since Python 3.10. Support for creating multiple processes in the `start` method will be removed in a future version of Tornado.

- **Changed in version 4.0**: Added `decompress_request`, `chunk_size`, `max_header_size`, `idle_connection_timeout`, `body_timeout`, `max_body_size` arguments. Added support for `HTTPServerConnectionDelegate` instances as `request_callback`.
- **Changed in version 4.1**: `HTTPServerConnectionDelegate.start_request` is now called with two arguments (`server_conn`, `request_conn`) (in accordance with the documentation) instead of one (`request_conn`).
- **Changed in version 4.2**: `HTTPServer` is now a subclass of `tornado.util.Configurable`.
- **Changed in version 4.5**: Added the `trusted_downstream` argument.
- **Changed in version 5.0**: The `io_loop` argument has been removed.

The public interface of this class is mostly inherited from `TCPServer` and is documented under that class.
coroutine close_all_connections() \rightarrow \text{None}

Close all open connections and asynchronously wait for them to finish.

This method is used in combination with \text{stop} to support clean shutdowns (especially for unittests). Typical usage would call \text{stop()} first to stop accepting new connections, then \text{await close_all_connections()} to wait for existing connections to finish.

This method does not currently close open websocket connections.

Note that this method is a coroutine and must be called with \text{await}.

6.3.2 \text{tornado.httpclient} — Asynchronous HTTP client

Blocking and non-blocking HTTP client interfaces.

This module defines a common interface shared by two implementations, \text{simple_httpclient} and \text{curl_httpclient}. Applications may either instantiate their chosen implementation class directly or use the \text{AsyncHTTPClient} class from this module, which selects an implementation that can be overridden with the \text{AsyncHTTPClient.configure} method.

The default implementation is \text{simple_httpclient}, and this is expected to be suitable for most users’ needs. However, some applications may wish to switch to \text{curl_httpclient} for reasons such as the following:

- \text{curl_httpclient} has some features not found in \text{simple_httpclient}, including support for HTTP proxies and the ability to use a specified network interface.
- \text{curl_httpclient} is more likely to be compatible with sites that are not-quite-compliant with the HTTP spec, or sites that use little-exercised features of HTTP.
- \text{curl_httpclient} is faster.

Note that if you are using \text{curl_httpclient}, it is highly recommended that you use a recent version of \text{libcurl} and \text{pycurl}. Currently the minimum supported version of \text{libcurl} is 7.22.0, and the minimum version of \text{pycurl} is 7.18.2. It is highly recommended that your \text{libcurl} installation is built with asynchronous DNS resolver (threaded or c-ares), otherwise you may encounter various problems with request timeouts (for more information, see \url{http://curl.haxx.se/libcurl/c/curl_easy_setopt.html#CURLOPTCONNECTTIMEOUTMS} and comments in \text{curl_httpclient.py}).

To select \text{curl_httpclient}, call \text{AsyncHTTPClient.configure} at startup:

\begin{verbatim}
AsyncHTTPClient.configure("tornado.curl_httpclient.CurlAsyncHTTPClient")
\end{verbatim}

\textbf{HTTP client interfaces}

class \text{tornado.httpclient.HTTPClient}(\text{async_client_class: Optional[Type[AsyncHTTPClient]]} = \text{None},
\text{**kwargs: Any})

A blocking HTTP client.

This interface is provided to make it easier to share code between synchronous and asynchronous applications. Applications that are running an \text{IOLoop} must use \text{AsyncHTTPClient} instead.

Typical usage looks like this:

\begin{verbatim}
http_client = httpclient.HTTPClient()
try:
    response = http_client.fetch("http://www.google.com/")
    print(response.body)
except httpclient.HTTPError as e:
(continues on next page)
\end{verbatim}
# HTTPError is raised for non-200 responses; the response
# can be found in e.response.
print("Error: " + str(e))

except Exception as e:
    # Other errors are possible, such as IOError.
    print("Error: " + str(e))
http_client.close()

Changed in version 5.0: Due to limitations in asyncio, it is no longer possible to use the synchronous HTTPClient while an IOLoop is running. Use AsyncHTTPClient instead.

close() → None
Closes the HTTPClient, freeing any resources used.

fetch(request: Union[HTTPRequest, str], **kwargs: Any) → HTTPResponse
Executes a request, returning an HTTPResponse.

The request may be either a string URL or an HTTPRequest object. If it is a string, we construct an HTTPRequest using any additional kwargs: HTTPRequest(request, **kwargs)

If an error occurs during the fetch, we raise an HTTPError unless the raise_error keyword argument is set to False.

class tornado.httpclient.AsyncHTTPClient(force_instance: bool = False, **kwargs: Any)
An non-blocking HTTP client.

Example usage:

```python
async def f():
    http_client = AsyncHTTPClient()
    try:
        response = await http_client.fetch("http://www.google.com")
    except Exception as e:
        print("Error: %s" % e)
    else:
        print(response.body)
```

The constructor for this class is magic in several respects: It actually creates an instance of an implementation-specific subclass, and instances are reused as a kind of pseudo-singleton (one per IOLoop). The keyword argument force_instance=True can be used to suppress this singleton behavior. Unless force_instance=True is used, no arguments should be passed to the AsyncHTTPClient constructor. The implementation subclass as well as arguments to its constructor can be set with the static method configure()

All AsyncHTTPClient implementations support a defaults keyword argument, which can be used to set default values for HTTPRequest attributes. For example:

```python
AsyncHTTPClient.configure(
    None, defaults=dict(user_agent="MyUserAgent"))
# or with force_instance:
client = AsyncHTTPClient(force_instance=True,
    defaults=dict(user_agent="MyUserAgent"))
```

Changed in version 5.0: The io_loop argument (deprecated since version 4.1) has been removed.

```close() → None
Destroys this HTTP client, freeing any file descriptors used.
```
This method is **not needed in normal use** due to the way that `AsyncHTTPClient` objects are transparently reused. `close()` is generally only necessary when either the `IOLoop` is also being closed, or the `force_instance=True` argument was used when creating the `AsyncHTTPClient`.

No other methods may be called on the `AsyncHTTPClient` after `close()`.

```python
fetch(request: Union[str, HTTPRequest], raise_error: bool = True, **kwargs: Any) → Future[HTTPResponse]
```

Executes a request, asynchronously returning an `HTTPResponse`.

The request may be either a string URL or an `HTTPRequest` object. If it is a string, we construct an `HTTPRequest` using any additional kwargs: `HTTPRequest(request, **kwargs)`

This method returns a `Future` whose result is an `HTTPResponse`. By default, the `Future` will raise an `HTTPError` if the request returned a non-200 response code (other errors may also be raised if the server could not be contacted). Instead, if `raise_error` is set to False, the response will always be returned regardless of the response code.

If a callback is given, it will be invoked with the `HTTPResponse`. In the callback interface, `HTTPError` is not automatically raised. Instead, you must check the response’s `error` attribute or call its `rethrow` method.

Changed in version 6.0: The callback argument was removed. Use the returned `Future` instead.

The `raise_error=False` argument only affects the `HTTPError` raised when a non-200 response code is used, instead of suppressing all errors.

```python
classmethod configure(impl: Union[None, str, Type[Configurable]], **kwargs: Any) → None
```

Configures the `AsyncHTTPClient` subclass to use.

`AsyncHTTPClient()` actually creates an instance of a subclass. This method may be called with either a class object or the fully-qualified name of such a class (or `None` to use the default, `SimpleAsyncHTTPClient`)

If additional keyword arguments are given, they will be passed to the constructor of each subclass instance created. The keyword argument `max_clients` determines the maximum number of simultaneous `fetch()` operations that can execute in parallel on each `IOLoop`. Additional arguments may be supported depending on the implementation class in use.

Example:

```python
AsyncHTTPClient.configure("tornado.curl_httpclient.CurlAsyncHTTPClient")
```
Request objects

HTTP client request object.

All parameters except url are optional.

Parameters

- **url (str)** – URL to fetch
- **method (str)** – HTTP method, e.g. “GET” or “POST”
- **headers (HTTPHeaders or dict)** – Additional HTTP headers to pass on the request
- **body (str or bytes)** – HTTP request body as a string (byte or unicode; if unicode the utf-8 encoding will be used)
- **body_producer (collections.abc.Callable)** – Callable used for lazy/asynchronous request bodies. It is called with one argument, a write function, and should return a Future. It should call the write function with new data as it becomes available. The write function returns a Future which can be used for flow control. Only one of body and body_producer may be specified. body_producer is not supported on curl_httpclient. When using body_producer it is recommended to pass a Content-Length in the headers as otherwise chunked encoding will be used, and many servers do not support chunked encoding on requests. New in Tornado 4.0
- **auth_username (str)** – Username for HTTP authentication
- **auth_password (str)** – Password for HTTP authentication
- **auth_mode (str)** – Authentication mode; default is “basic”. Allowed values are implementation-defined; curl_httpclient supports “basic” and “digest”; simple_httpclient only supports “basic”
• `connect_timeout (float)` – Timeout for initial connection in seconds, default 20 seconds (0 means no timeout)

• `request_timeout (float)` – Timeout for entire request in seconds, default 20 seconds (0 means no timeout)

• `if_modified_since (datetime or float)` – Timestamp for If-Modified-Since header

• `follow_redirections (bool)` – Should redirects be followed automatically or return the 3xx response? Default True.

• `max_redirects (int)` – Limit for `follow_redirections`, default 5.

• `user_agent (str)` – String to send as User-Agent header

• `decompress_response (bool)` – Request a compressed response from the server and decompress it after downloading. Default is True. New in Tornado 4.0.

• `use_gzip (bool)` – Deprecated alias for `decompress_response` since Tornado 4.0.

• `network_interface (str)` – Network interface or source IP to use for request. See curl_httpclient note below.

• `streaming_callback (collections.abc.Callable)` – If set, `streaming_callback` will be run with each chunk of data as it is received, and HTTPResponse.body and HTTPResponse.buffer will be empty in the final response.

• `header_callback (collections.abc.Callable)` – If set, `header_callback` will be run with each header line as it is received (including the first line, e.g. HTTP/1.0 200 OK\r\n, and a final line containing only \r\n. All lines include the trailing newline characters). HTTPResponse.headers will be empty in the final response. This is most useful in conjunction with `streaming_callback`, because it’s the only way to get access to header data while the request is in progress.

• `prepare_curl_callback (collections.abc.Callable)` – If set, will be called with a pycurl.Curl object to allow the application to make additional `setopt` calls.

• `proxy_host (str)` – HTTP proxy hostname. To use proxies, `proxy_host` and `proxy_port` must be set; `proxy_username`, `proxy_password` and `proxy_auth_mode` are optional. Proxies are currently only supported with curl_httpclient.

• `proxy_port (int)` – HTTP proxy port

• `proxy_username (str)` – HTTP proxy username

• `proxy_password (str)` – HTTP proxy password

• `proxy_auth_mode (str)` – HTTP proxy Authentication mode; default is “basic”. supports “basic” and “digest”

• `allow_nonstandard_methods (bool)` – Allow unknown values for `method` argument? Default is False.

• `validate_cert (bool)` – For HTTPS requests, validate the server’s certificate? Default is True.

• `ca_certs (str)` – filename of CA certificates in PEM format, or None to use defaults. See note below when used with curl_httpclient.

• `client_key (str)` – Filename for client SSL key, if any. See note below when used with curl_httpclient.

• `client_cert (str)` – Filename for client SSL certificate, if any. See note below when used with curl_httpclient.
• **ssl_options** (*ssl.SSLContext*) – *ssl.SSLContext* object for use in `simple_httpclient` (unsupported by `curl_httpclient`). Overrides `validate_cert`, `ca_certs`, `client_key`, and `client_cert`.

• **allow_ipv6** (*bool*) – Use IPv6 when available? Default is True.

• **expect_100_continue** (*bool*) – If true, send the Expect: **100-continue** header and wait for a continue response before sending the request body. Only supported with `simple_httpclient`.

**Note:** When using `curl_httpclient` certain options may be inherited by subsequent fetches because `pycurl` does not allow them to be cleanly reset. This applies to the `ca_certs`, `client_key`, `client_cert`, and `network_interface` arguments. If you use these options, you should pass them on every request (you don’t have to always use the same values, but it’s not possible to mix requests that specify these options with ones that use the defaults).

New in version 3.1: The `auth_mode` argument.

New in version 4.0: The `body_producer` and `expect_100_continue` arguments.

New in version 4.2: The `ssl_options` argument.

New in version 4.5: The `proxy_auth_mode` argument.

### Response objects

**class**  [tornado.httpclient.HTTPResponse](http://tornadoinc.com/)

```python
```

HTTP Response object.

**Attributes:**

• **request**: HTTPRequest object

• **code**: numeric HTTP status code, e.g. 200 or 404

• **reason**: human-readable reason phrase describing the status code

• **headers**: [tornado.httputil.HTTPHeaders](http://tornadoinc.com/) object

• **effective_url**: final location of the resource after following any redirects

• **buffer**: cStringIO object for response body

• **body**: response body as bytes (created on demand from `self.buffer`)

• **error**: Exception object, if any

• **request_time**: seconds from request start to finish. Includes all network operations from DNS resolution to receiving the last byte of data. Does not include time spent in the queue (due to the `max_clients` option). If redirects were followed, only includes the final request.

• **start_time**: Time at which the HTTP operation started, based on `time.time` (not the monotonic clock used by `IOLoop.time`). May be `None` if the request timed out while in the queue.
• **time info**: dictionary of diagnostic timing information from the request. Available data are subject to change, but currently uses timings available from http://curl.haxx.se/libcurl/c/curl_easy_getinfo.html, plus queue, which is the delay (if any) introduced by waiting for a slot under `AsyncHTTPClient`'s `max_clients` setting.

New in version 5.1: Added the `start_time` attribute.

Changed in version 5.1: The `request_time` attribute previously included time spent in the queue for `simple_httpclient`, but not in `curl_httpclient`. Now queueing time is excluded in both implementations. `request_time` is now more accurate for `curl_httpclient` because it uses a monotonic clock when available.

```python
def rethrow() -> None
    if there was an error on the request, raise an `HTTPError`.
```

### Exceptions

**exception** `tornado.httpclient.HTTPClientError`(*code: int, message: Optional[str] = None, response: Optional[`HTTPResponse`] = None*)

Exception thrown for an unsuccessful HTTP request.

Attributes:

- **code** - HTTP error integer error code, e.g. 404. Error code 599 is used when no HTTP response was received, e.g. for a timeout.
- **response** - `HTTPResponse` object, if any.

Note that if `follow redirects` is False, redirects become HTTPErrors, and you can look at `error.response.headers['Location']` to see the destination of the redirect.

Changed in version 5.1: Renamed from `HTTPError` to `HTTPClientError` to avoid collisions with `tornado.web.HTTPError`. The name `tornado.httpclient.HTTPError` remains as an alias.

**exception** `tornado.httpclient.HTTPError`

Alias for `HTTPClientError`.

### Command-line interface

This module provides a simple command-line interface to fetch a url using Tornado's HTTP client. Example usage:

```
# Fetch the url and print its body
python -m tornado.httpclient http://www.google.com

# Just print the headers
python -m tornado.httpclient --print_headers --print_body=false http://www.google.com
```
Implementations

class tornado.simple_httpclient.SimpleAsyncHTTPClient(force_instance: bool = False, **kwargs: Any)
Non-blocking HTTP client with no external dependencies.

This class implements an HTTP 1.1 client on top of Tornado’s IOStreams. Some features found in the curl-based
AsyncHTTPClient are not yet supported. In particular, proxies are not supported, connections are not reused,
and callers cannot select the network interface to be used.

This implementation supports the following arguments, which can be passed to configure() to control the
global singleton, or to the constructor when force_instance=True.

max_clients is the number of concurrent requests that can be in progress; when this limit is reached additional
requests will be queued. Note that time spent waiting in this queue still counts against the request_timeout.

defaults is a dict of parameters that will be used as defaults on all HTTPRequest objects submitted to this
client.

hostname_mapping is a dictionary mapping hostnames to IP addresses. It can be used to make local DNS
changes when modifying system-wide settings like /etc/hosts is not possible or desirable (e.g. in unittests).
resolver is similar, but using the Resolver interface instead of a simple mapping.

max_buffer_size (default 100MB) is the number of bytes that can be read into memory at once.
max_body_size (defaults to max_buffer_size) is the largest response body that the client will accept. With-
out a streaming_callback, the smaller of these two limits applies; with a streaming_callback only
max_body_size does.

Changed in version 4.2: Added the max_body_size argument.

class tornado.curl_httpclient.CurlAsyncHTTPClient(max_clients=10, defaults=None)
libcurl-based HTTP client.

This implementation supports the following arguments, which can be passed to configure() to control the
global singleton, or to the constructor when force_instance=True.

max_clients is the number of concurrent requests that can be in progress; when this limit is reached additional
requests will be queued.

defaults is a dict of parameters that will be used as defaults on all HTTPRequest objects submitted to this
client.

Example Code

• A simple webspider shows how to fetch URLs concurrently.
• The file uploader demo uses either HTTP POST or HTTP PUT to upload files to a server.

6.3.3 tornado.httputil — Manipulate HTTP headers and URLs

HTTP utility code shared by clients and servers.

This module also defines the HTTPServerRequest class which is exposed via tornado.web.RequestHandler.
request.

class tornado.httputil.HTTPHeaders(__arg: Mapping[str, List[str]])
class tornado.httputil.HTTPHeaders(__arg: Mapping[str, str])
class tornado.httputil.HTTPHeaders(*args: Tuple[str, str])
class tornado.httputil.HTTPHeaders(**kwargs: str)

A dictionary that maintains Http-Header-Case for all keys.

Supports multiple values per key via a pair of new methods, `add()` and `get_list()`. The regular dictionary interface returns a single value per key, with multiple values joined by a comma.

```python
g = HTTPHeaders({'content-type': 'text/html'})
g.keys()  # ['Content-Type']
g['content-type']  # 'text/html'
g.add('Set-Cookie', 'A=B')
g.add('Set-Cookie', 'C=D')
g['set-cookie']  # 'A=B,C=D'
g.get_list('set-cookie')  # ['A=B', 'C=D']
```

```python
for (k,v) in sorted(g.get_all()):
    print('%s: %s
    ' % (k,v))
    Content-Type: text/html
    Set-Cookie: A=B
    Set-Cookie: C=D
```

`add(name: str, value: str) → None`

Adds a new value for the given key.

`get_list(name: str) → List[str]`

Returns all values for the given header as a list.

`get_all() → Iterable[Tuple[str, str]]`

Returns an iterable of all (name, value) pairs.

If a header has multiple values, multiple pairs will be returned with the same name.

`parse_line(line: str) → None`

Updates the dictionary with a single header line.

```python
g = HTTPHeaders()
g.parse_line('Content-Type: text/html')
g.get('content-type')  # 'text/html'
```

`classmethod parse(headers: str) → HTTPHeaders`

Returns a dictionary from HTTP header text.

```python
g = HTTPHeaders.parse('Content-Type: text/html\nContent-Length: 42')
s = sorted(g.items())
[(Content-Length, '42'), ('Content-Type', 'text/html')]
```

Changed in version 5.1: Raises HTTPInputError on malformed headers instead of a mix of KeyError, and ValueError.

6.3. HTTP servers and clients
class tornado.httputil.HTTPServerRequest:

A single HTTP request.

All attributes are type str unless otherwise noted.

**method**
HTTP request method, e.g. “GET” or “POST”

**uri**
The requested uri.

**path**
The path portion of uri.

**query**
The query portion of uri.

**version**
HTTP version specified in request, e.g. “HTTP/1.1”

**headers**
HTTPHeaders dictionary-like object for request headers. Acts like a case-insensitive dictionary with additional methods for repeated headers.

**body**
Request body, if present, as a byte string.

**remote_ip**
Client’s IP address as a string. If HTTPServer.xheaders is set, will pass along the real IP address provided by a load balancer in the X-Real-Ip or X-Forwarded-For header.

Changed in version 3.1: The list format of X-Forwarded-For is now supported.

**protocol**
The protocol used, either “http” or “https”. If HTTPServer.xheaders is set, will pass along the protocol used by a load balancer if reported via an X-Scheme header.

**host**
The requested hostname, usually taken from the Host header.

**arguments**
GET/POST arguments are available in the arguments property, which maps arguments names to lists of values (to support multiple values for individual names). Names are of type str, while arguments are byte strings. Note that this is different from RequestHandler.get_argument, which returns argument values as unicode strings.

**query_arguments**
Same format as arguments, but contains only arguments extracted from the query string.

New in version 3.2.
body_arguments
Same format as arguments, but contains only arguments extracted from the request body.
New in version 3.2.

files
File uploads are available in the files property, which maps file names to lists of HTTPFile.

connection
An HTTP request is attached to a single HTTP connection, which can be accessed through the “connection” attribute. Since connections are typically kept open in HTTP/1.1, multiple requests can be handled sequentially on a single connection.

Changed in version 4.0: Moved from tornado.httpserver.HTTPRequest.

property cookies: Dict[str, Morsel]
A dictionary of http.cookies.Morsel objects.

full_url() → str
Reconstructs the full URL for this request.

request_time() → float
Returns the amount of time it took for this request to execute.

get_ssl_certificate(binary_form: bool = False) → Union[None, Dict, bytes]
Returns the client’s SSL certificate, if any.

To use client certificates, the HTTPServer’s ssl.SSLContext.verify_mode field must be set, e.g.:

```python
ssl_ctx = ssl.create_default_context(ssl.Purpose.CLIENT_AUTH)
ssl_ctx.load_cert_chain("foo.crt", "foo.key")
ssl_ctx.load_verify_locations(“cacerts.pem”)  
ssl_ctx.verify_mode = ssl.CERT_REQUIRED
server = HTTPServer(app, ssl_options=ssl_ctx)
```

By default, the return value is a dictionary (or None, if no client certificate is present). If binary_form is true, a DER-encoded form of the certificate is returned instead. See SSLServer.getpeerinfo() in the standard library for more details. http://docs.python.org/library/ssl.html#sslsocket-objects

exception tornado.httputil.HTTPInputError
Exception class for malformed HTTP requests or responses from remote sources.
New in version 4.0.

exception tornado.httputil.HTTPOutputError
Exception class for errors in HTTP output.
New in version 4.0.

class tornado.httputil.HTTPServerConnectionDelegate
Implement this interface to handle requests from HTTPServer.
New in version 4.0.

start_request(server_conn: object, request_conn: HTTPConnection) → HTTPMessageDelegate
This method is called by the server when a new request has started.

Parameters
• server_conn – is an opaque object representing the long-lived (e.g. tcp-level) connection.

6.3. HTTP servers and clients 95
• **request_conn** – is a `HTTPConnection` object for a single request/response exchange.

  This method should return a `HTTPMessageDelegate`.

  **on_close**(server_conn: object) → None

  This method is called when a connection has been closed.

  **Parameters**

  server_conn – is a server connection that has previously been passed to `start_request`.

  **class** `tornado.httputil.HTTPMessageDelegate`  
  
  Implement this interface to handle an HTTP request or response.

  New in version 4.0.

  **headers_received**(start_line: Union[RequestStartLine, ResponseStartLine], headers: HTTPHeaders) → Optional[Awaitable[None]]

  Called when the HTTP headers have been received and parsed.

  **Parameters**

  • start_line – a `RequestStartLine` or `ResponseStartLine` depending on whether this is a client or server message.
  
  • headers – a `HTTPHeaders` instance.

  Some `HTTPConnection` methods can only be called during `headers_received`.

  May return a `Future`; if it does the body will not be read until it is done.

  **data_received**(chunk: bytes) → Optional[Awaitable[None]]

  Called when a chunk of data has been received.

  May return a `Future` for flow control.

  **finish**() → None

  Called after the last chunk of data has been received.

  **on_connection_close**() → None

  Called if the connection is closed without finishing the request.

  If `headers_received` is called, either `finish` or `on_connection_close` will be called, but not both.

  **class** `tornado.httputil.HTTPConnection`  
  
  Applications use this interface to write their responses.

  New in version 4.0.

  **write_headers**(start_line: Union[RequestStartLine, ResponseStartLine], headers: HTTPHeaders, chunk: Optional[bytes] = None) → Future[None]

  Write an HTTP header block.

  **Parameters**

  • start_line – a `RequestStartLine` or `ResponseStartLine`.
  
  • headers – a `HTTPHeaders` instance.
  
  • chunk – the first (optional) chunk of data. This is an optimization so that small responses can be written in the same call as their headers.

  The version field of start_line is ignored.

  Returns a future for flow control.
write(chunk: bytes) → Future[None]

Writes a chunk of body data.

Returns a future for flow control.

Changed in version 6.0: The callback argument was removed.

finish() → None

Indicates that the last body data has been written.

tornado.httputil.url_concat(url: str, args: Union[None, Dict[str, str], List[Tuple[str, str]], Tuple[Tuple[str, str], ...]]) → str

Concatenate url and arguments regardless of whether url has existing query parameters.

args may be either a dictionary or a list of key-value pairs (the latter allows for multiple values with the same key.

```python
>>> url_concat("http://example.com/foo", dict(c="d"))
'http://example.com/foo?c=d'
>>> url_concat("http://example.com/foo?a=b", dict(c="d"))
'http://example.com/foo?a=b&c=d'
>>> url_concat("http://example.com/foo?a=b", ["c", "d"], ["c", "d2"])
'http://example.com/foo?a=b&c=d&c=d2'
```

class tornado.httputil.HTTPFile

Represents a file uploaded via a form.

For backwards compatibility, its instance attributes are also accessible as dictionary keys.

- filename
- body
- content_type

Parses a form request body.

Supports application/x-www-form-urlencoded and multipart/form-data. The content_type parameter should be a string and body should be a byte string. The arguments and files parameters are dictionaries that will be updated with the parsed contents.

tornado.httputil.parse_multipart_form_data(boundary: bytes, data: bytes, arguments: Dict[str, List[bytes]], files: Dict[str, List[HTTPFile]]) → None

Parses a multipart/form-data body.

The boundary and data parameters are both byte strings. The dictionaries given in the arguments and files parameters will be updated with the contents of the body.

Changed in version 5.1: Now recognizes non-ASCII filenames in RFC 2231/5987 (filename*) format.

tornado.httputil.format_timestamp(ts: Union[int, float, tuple, struct_time, datetime]) → str

Formats a timestamp in the format used by HTTP.

The argument may be a numeric timestamp as returned by time.time, a timestamp as returned by time.gmtime, or a datetime.datetime object. Naive datetime.datetime objects are assumed to represent UTC; aware objects are converted to UTC before formatting.

6.3. HTTP servers and clients
```python
>>> format_timestamp(1359312200)
'Sun, 27 Jan 2013 18:43:20 GMT'
```

class `tornado.httputil.RequestStartLine`(*method*, *path*, *version*)

Create new instance of `RequestStartLine`(*method*, *path*, *version*)

```
def __init__(self, *method*, *path*, *version*):
    self.method = method
    self.path = path
    self.version = version
```

method

Alias for field number 0

path

Alias for field number 1

version

Alias for field number 2

tornado.httputil.parse_request_start_line(*line*) -> `RequestStartLine`

Returns a (method, path, version) tuple for an HTTP 1.x request line.

The response is a `collections.namedtuple`.

```python
>>> parse_request_start_line("GET /foo HTTP/1.1")
RequestStartLine(method='GET', path='/foo', version='HTTP/1.1')
```

class `tornado.httputil.ResponseStartLine`(*version*, *code*, *reason*)

Create new instance of `ResponseStartLine`(*version*, *code*, *reason*)

```
def __init__(self, *version*, *code*, *reason*):
    self.version = version
    self.code = code
    self.reason = reason
```

code

Alias for field number 1

reason

Alias for field number 2

version

Alias for field number 0

tornado.httputil.parse_response_start_line(*line*) -> `ResponseStartLine`

Returns a (version, code, reason) tuple for an HTTP 1.x response line.

The response is a `collections.namedtuple`.

```python
>>> parse_response_start_line("HTTP/1.1 200 OK")
ResponseStartLine(version='HTTP/1.1', code=200, reason='OK')
```

tornado.httputil.encode_username_password(*username*, *password*) -> `bytes`

Encodes a username/password pair in the format used by HTTP auth.

The return value is a byte string in the form `username:password`.

New in version 5.1.
tornado.httputil.split_host_and_port(netloc: str) → Tuple[str, Optional[int]]

Returns (host, port) tuple from netloc.

Returned port will be None if not present.

New in version 4.1.

tornado.httputil.qs_to_qsl(qs: Dict[str, List]) → Iterable[Tuple[str, AnyStr]]

Generator converting a result of parse_qs back to name-value pairs.

New in version 5.0.

tornado.httputil.parse_cookie(cookie: str) → Dict[str, str]

Parse a Cookie HTTP header into a dict of name/value pairs.

This function attempts to mimic browser cookie parsing behavior; it specifically does not follow any of the
cookie-related RFCs (because browsers don’t either).

The algorithm used is identical to that used by Django version 1.9.10.

New in version 4.4.2.

6.3.4 tornado.http1connection – HTTP/1.x client/server implementation

Client and server implementations of HTTP/1.x.

New in version 4.0.

Parameters for HTTP1Connection and HTTP1ServerConnection.

Parameters

• no_keep_alive (bool) – If true, always close the connection after one request.
• chunk_size (int) – how much data to read into memory at once
• max_header_size (int) – maximum amount of data for HTTP headers
• header_timeout (float) – how long to wait for all headers (seconds)
• max_body_size (int) – maximum amount of data for body
• body_timeout (float) – how long to wait while reading body (seconds)
• decompress (bool) – if true, decode incoming Content-Encoding: gzip

class tornado.http1connection.HTTP1Connection(stream: IOStream, is_client: bool, params: Optional[HTTP1ConnectionParameters] = None, context: Optional[object] = None)

Implements the HTTP/1.x protocol.

This class can be on its own for clients, or via HTTP1ServerConnection for servers.

Parameters

• stream – an IOStream

6.3. HTTP servers and clients
• **is_client** *(bool)* – client or server

• **params** – a `HTTP1ConnectionParameters` instance or `None`

• **context** – an opaque application-defined object that can be accessed as connection.

```
read_response(delegate: HTTPMessageDelegate) \arrow\ Awaitable[bool]
```

Read a single HTTP response.

Typical client-mode usage is to write a request using `write_headers`, `write`, and `finish`, and then call `read_response`.

**Parameters**

`delegate` – a `HTTPMessageDelegate`

Returns a `Future` that resolves to a bool after the full response has been read. The result is true if the stream is still open.

```
set_close_callback(callback: Optional[Callable[[], None]]) \arrow\ None
```

Sets a callback that will be run when the connection is closed.

Note that this callback is slightly different from `HTTPMessageDelegate.on_connection_close`: The `HTTPMessageDelegate` method is called when the connection is closed while receiving a message. This callback is used when there is not an active delegate (for example, on the server side this callback is used if the client closes the connection after sending its request but before receiving all the response.

```
detach() \arrow\ IOStream
```

Take control of the underlying stream.

Returns the underlying `IOStream` object and stops all further HTTP processing. May only be called during `HTTPMessageDelegate.headers_received`. Intended for implementing protocols like websockets that tunnel over an HTTP handshake.

```
set_body_timeout(timeout: float) \arrow\ None
```

Sets the body timeout for a single request.

Overrides the value from `HTTP1ConnectionParameters`.

```
set_max_body_size(max_body_size: int) \arrow\ None
```

Sets the body size limit for a single request.

Overrides the value from `HTTP1ConnectionParameters`.

```
write_headers(start_line: Union[RequestStartLine, ResponseStartLine], headers: HTTPHeaders, chunk: Optional[bytes] = None) \arrow\ Future[None]
```

Implements `HTTPConnection.write_headers`.

```
write(chunk: bytes) \arrow\ Future[None]
```

Implements `HTTPConnection.write`.

For backwards compatibility it is allowed but deprecated to skip `write_headers` and instead call `write()` with a pre-encoded header block.

```
finish() \arrow\ None
```

Implements `HTTPConnection.finish`.

```
class tornado.http1connection.HTTP1ServerConnection(stream: IOStream, params: Optional[HTTP1ConnectionParameters] = None, context: Optional[object] = None)
```

An HTTP/1.x server.
Parameters

- **stream** – an `IOStream`
- **params** – a `HTTP1ConnectionParameters` or None
- **context** – an opaque application-defined object that is accessible as `connection.context`

**coroutine close**() → `None`

Closes the connection.

Returns a Future that resolves after the serving loop has exited.

**start_serving**(**delegate**: `HTTPServerConnectionDelegate**) → `None`

Starts serving requests on this connection.

**Parameters**

- **delegate** – a `HTTPServerConnectionDelegate`

---

### 6.4 Asynchronous networking

#### 6.4.1 tornado.ioloop — Main event loop

An I/O event loop for non-blocking sockets.

In Tornado 6.0, `IOLoop` is a wrapper around the `asyncio` event loop, with a slightly different interface. The `IOLoop` interface is now provided primarily for backwards compatibility; new code should generally use the `asyncio` event loop interface directly. The `IOLoop.current` class method provides the `IOLoop` instance corresponding to the running `asyncio` event loop.

**IOLoop objects**

**class** `tornado.ioloop.IOLoop`(*args: Any, **kwargs: Any*)

An I/O event loop.

As of Tornado 6.0, `IOLoop` is a wrapper around the `asyncio` event loop.

Example usage for a simple TCP server:

```python
import asyncio
import errno
import functools
import socket
import tornado
from tornado.iostream import IOStream

async def handle_connection(connection, address):
    stream = IOStream(connection)
    message = await stream.read_until_close()
    print(f"message from client: {message.decode().strip()}"

def connection_ready(sock, fd, events):
    while True:
        try:
```

(continues on next page)
async def main():
    sock = socket.socket(socket.AF_INET, socket.SOCK_STREAM, 0)
    sock.setsockopt(socket.SOL_SOCKET, socket.SO_REUSEADDR, 1)
    sock.setblocking(0)
    sock.bind(('"", 8888))
    sock.listen(128)

    io_loop = tornado.ioloop.IOLoop.current()
    callback = functools.partial(connection_ready, sock)
    io_loop.add_handler(sock.fileno(), callback, io_loop.READ)

    await asyncio.Event().wait()

if __name__ == "__main__":
    asyncio.run(main())

Most applications should not attempt to construct an IOLoop directly, and instead initialize the asyncio event loop and use IOLoop.current(). In some cases, such as in test frameworks when initializing an IOLoop to be run in a secondary thread, it may be appropriate to construct an IOLoop with IOLoop(make_current=False).

In general, an IOLoop cannot survive a fork or be shared across processes in any way. When multiple processes are being used, each process should create its own IOLoop, which also implies that any objects which depend on the IOLoop (such as AsyncHTTPClient) must also be created in the child processes. As a guideline, anything that starts processes (including the tornado.process and multiprocessing modules) should do so as early as possible, ideally the first thing the application does after loading its configuration, and before any calls to IOLoop.start or asyncio.run.

Changed in version 4.2: Added the make_current keyword argument to the IOLoop constructor.

Changed in version 5.0: Uses the asyncio event loop by default. The IOLoop.configure method cannot be used on Python 3 except to redundantly specify the asyncio event loop.

Changed in version 6.3: make_current=True is now the default when creating an IOLoop - previously the default was to make the event loop current if there wasn’t already a current one.

Running an IOLoop

static IOLoop.current() → IOLoop

static IOLoop.current(instance: bool = True) → Optional[IOLoop]

Returns the current thread’s IOLoop.

If an IOLoop is currently running or has been marked as current by make_current, returns that instance. If there is no current IOLoop and instance is true, creates one.

Changed in version 4.1: Added instance argument to control the fallback to IOLoop.instance().

Changed in version 5.0: On Python 3, control of the current IOLoop is delegated to asyncio, with this and other methods as pass-through accessors. The instance argument now controls whether an IOLoop is created automatically when there is none, instead of whether we fall back to IOLoop.instance() (which is now an
alias for this method). instance=False is deprecated, since even if we do not create an IOLoop, this method may initialize the asyncio loop.

Deprecated since version 6.2: It is deprecated to call IOLoop.current() when no asyncio event loop is running.

IOLoop.make_current() → None

Makes this the IOLoop for the current thread.

An IOLoop automatically becomes current for its thread when it is started, but it is sometimes useful to call make_current explicitly before starting the IOLoop, so that code run at startup time can find the right instance.

Changed in version 4.1: An IOLoop created while there is no current IOLoop will automatically become current.

Changed in version 5.0: This method also sets the current asyncio event loop.

Deprecated since version 6.2: Setting and clearing the current event loop through Tornado is deprecated. Use asyncio.set_event_loop instead if you need this.

static IOLoop.clear_current() → None

Clears the IOLoop for the current thread.

Intended primarily for use by test frameworks in between tests.

Changed in version 5.0: This method also clears the current asyncio event loop.

Deprecated since version 6.2.

IOLoop.start() → None

Starts the I/O loop.

The loop will run until one of the callbacks calls stop(), which will make the loop stop after the current event iteration completes.

IOLoop.stop() → None

Stop the I/O loop.

If the event loop is not currently running, the next call to start() will return immediately.

Note that even after stop has been called, the IOLoop is not completely stopped until IOLoop.start has also returned. Some work that was scheduled before the call to stop may still be run before the IOLoop shuts down.

IOLoop.run_sync(func: Callable, timeout: Optional[float] = None) → Any

Starts the IOLoop, runs the given function, and stops the loop.

The function must return either an awaitable object or None. If the function returns an awaitable object, the IOLoop will run until the awaitable is resolved (and run_sync() will return the awaitable’s result). If it raises an exception, the IOLoop will stop and the exception will be re-raised to the caller.

The keyword-only argument timeout may be used to set a maximum duration for the function. If the timeout expires, an asyncio.TimeoutError is raised.

This method is useful to allow asynchronous calls in a main() function:

```
async def main():
    # do stuff...
    if __name__ == '__main__':
        IOLoop.current().run_sync(main)
```

Changed in version 4.3: Returning a non-None, non-awaitable value is now an error.

Changed in version 5.0: If a timeout occurs, the func coroutine will be cancelled.
Changed in version 6.2: `tornado.util.TimeoutError` is now an alias to `asyncio.TimeoutError`.

```python
IOLoop.close(all_fds: bool = False) → None
```

Closes the `IOLoop`, freeing any resources used.

If `all_fds` is true, all file descriptors registered on the IOLoop will be closed (not just the ones created by the `IOLoop` itself).

Many applications will only use a single `IOLoop` that runs for the entire lifetime of the process. In that case closing the `IOLoop` is not necessary since everything will be cleaned up when the process exits. `IOLoop.close` is provided mainly for scenarios such as unit tests, which create and destroy a large number of `IOLoops`.

An `IOLoop` must be completely stopped before it can be closed. This means that `IOLoop.stop()` must be called and `IOLoop.start()` must be allowed to return before attempting to call `IOLoop.close()`. Therefore the call to `close` will usually appear just after the call to `start` rather than near the call to `stop`.

Changed in version 3.1: If the `IOLoop` implementation supports non-integer objects for “file descriptors”, those objects will have their `close` method when `all_fds` is true.

```python
static IOLoop.instance() → IOLoop
```

Deprecated alias for `IOLoop.current()`.

Changed in version 5.0: Previously, this method returned a global singleton `IOLoop`, in contrast with the per-thread `IOLoop` returned by `current()`. In nearly all cases the two were the same (when they differed, it was generally used from non-Tornado threads to communicate back to the main thread’s `IOLoop`). This distinction is not present in `asyncio`, so in order to facilitate integration with that package `instance()` was changed to be an alias to `current()`. Applications using the cross-thread communications aspect of `instance()` should instead set their own global variable to point to the `IOLoop` they want to use.

Deprecated since version 5.0.

```python
IOLoop.install() → None
```

Deprecated alias for `make_current()`.

Changed in version 5.0: Previously, this method would set this `IOLoop` as the global singleton used by `IOLoop.instance()`. Now that `instance()` is an alias for `current()`, `install()` is an alias for `make_current()`.

Deprecated since version 5.0.

```python
static IOLoop.clear_instance() → None
```

Deprecated alias for `clear_current()`.

Changed in version 5.0: Previously, this method would clear the `IOLoop` used as the global singleton by `IOLoop.instance()`. Now that `instance()` is an alias for `current()`, `clear_instance()` is an alias for `clear_current()`.

Deprecated since version 5.0.

**I/O events**

```python
IOLoop.add_handler(fd: int, handler: Callable[[int, int], None], events: int) → None
```

Registers the given handler to receive the given events for `fd`.

The `fd` argument may either be an integer file descriptor or a file-like object with a `fileno()` and `close()` method.

The `events` argument is a bitwise or of the constants `IOLoop.READ`, `IOLoop.WRITE`, and `IOLoop.ERROR`.

When an event occurs, `handler(fd, events)` will be run.
Changed in version 4.0: Added the ability to pass file-like objects in addition to raw file descriptors.

```python
IOLoop.update_handler(fd: Union[int, _Selectable], events: int) \rightarrow None
```
Changes the events we listen for `fd`.

Changed in version 4.0: Added the ability to pass file-like objects in addition to raw file descriptors.

```python
IOLoop.remove_handler(fd: Union[int, _Selectable]) \rightarrow None
```
Stop listening for events on `fd`.

Changed in version 4.0: Added the ability to pass file-like objects in addition to raw file descriptors.

**Callbacks and timeouts**

```python
IOLoop.add_callback(callback: Callable, *args: Any, **kwargs: Any) \rightarrow None
```
Calls the given callback on the next I/O loop iteration.

It is safe to call this method from any thread at any time, except from a signal handler. Note that this is the only method in `IOLoop` that makes this thread-safety guarantee; all other interaction with the `IOLoop` must be done from that `IOLoop`'s thread. `add_callback()` may be used to transfer control from other threads to the `IOLoop`'s thread.

```python
IOLoop.add_callback_from_signal(callback: Callable, *args: Any, **kwargs: Any) \rightarrow None
```
Calls the given callback on the next I/O loop iteration.

Intended to be safe for use from a Python signal handler; should not be used otherwise.

Deprecated since version 6.4: Use `asyncio.AbstractEventLoop.add_signal_handler` instead. This method is suspected to have been broken since Tornado 5.0 and will be removed in version 7.0.

```python
IOLoop.add_future(future: Union[Future[_T], concurrent.futures.Future[_T]], callback: Callable[[Future[_T]], None]) \rightarrow None
```
Schedules a callback on the `IOLoop` when the given `Future` is finished.

The callback is invoked with one argument, the `Future`.

This method only accepts `Future` objects and not other awaitables (unlike most of Tornado where the two are interchangeable).

```python
IOLoop.add_timeout(deadline: Union[float, timedelta], callback: Callable, *args: Any, **kwargs: Any) \rightarrow object
```
Runs the callback at the time deadline from the I/O loop.

Returns an opaque handle that may be passed to `remove_timeout` to cancel.

deadline may be a number denoting a time (on the same scale as `IOLoop.time`, normally `time.time`), or a `datetime.timedelta` object for a deadline relative to the current time. Since Tornado 4.0, `call_later` is a more convenient alternative for the relative case since it does not require a timedelta object.

Note that it is not safe to call `add_timeout` from other threads. Instead, you must use `add_callback` to transfer control to the `IOLoop`'s thread, and then call `add_timeout` from there.

Subclasses of `IOLoop` must implement either `add_timeout` or `call_at`; the default implementations of each will call the other. `call_at` is usually easier to implement, but subclasses that wish to maintain compatibility with Tornado versions prior to 4.0 must use `add_timeout` instead.

Changed in version 4.0: Now passes through `*args` and `**kwargs` to the callback.
IOLoop.call_at(
    when: float, 
    callback: Callable, *args: Any, **kwargs: Any) -> object

Runs the callback at the absolute time designated by when.

when must be a number using the same reference point as IOLoop.time.

Returns an opaque handle that may be passed to remove_timeout to cancel. Note that unlike the asyncio method of the same name, the returned object does not have a cancel() method.

See add_timeout for comments on thread-safety and subclassing.

New in version 4.0.

IOLoop.call_later(
    delay: float, 
    callback: Callable, *args: Any, **kwargs: Any) -> object

Runs the callback after delay seconds have passed.

Returns an opaque handle that may be passed to remove_timeout to cancel. Note that unlike the asyncio method of the same name, the returned object does not have a cancel() method.

See add_timeout for comments on thread-safety and subclassing.

New in version 4.0.

IOLoop.remove_timeout(
    timeout: object) -> None

Cancels a pending timeout.

The argument is a handle as returned by add_timeout. It is safe to call remove_timeout even if the callback has already been run.

IOLoop.spawn_callback(
    callback: Callable, *args: Any, **kwargs: Any) -> None

Calls the given callback on the next IOLoop iteration.

As of Tornado 6.0, this method is equivalent to add_callback.

New in version 4.0.

IOLoop.run_in_executor(
    executor: Optional[Executor], 
    func: Callable[..., _T], *args: Any) -> Awaitable[_T]

Runs a function in a concurrent.futures.Executor. If executor is None, the IO loop’s default executor will be used.

Use functools.partial to pass keyword arguments to func.

New in version 5.0.

IOLoop.set_default_executor(
    executor: Executor) -> None

Sets the default executor to use with run_in_executor().

New in version 5.0.

IOLoop.time() -> float

Returns the current time according to the IOLoop's clock.

The return value is a floating-point number relative to an unspecified time in the past.

Historically, the IOLoop could be customized to use e.g. time.monotonic instead of time.time, but this is not currently supported and so this method is equivalent to time.time.

class tornado.ioloop.PeriodicCallback(
    callback: Callable[], Optional[Awaitable[]], callback_time: 
    Union[timedelta, float], jitter: float = 0)

Schedules the given callback to be called periodically.

The callback is called every callback_time milliseconds when callback_time is a float. Note that the timeout is given in milliseconds, while most other time-related functions in Tornado use seconds. callback_time may alternatively be given as a datetime.timedelta object.
If jitter is specified, each callback time will be randomly selected within a window of jitter \(\times\) callback_time milliseconds. Jitter can be used to reduce alignment of events with similar periods. A jitter of 0.1 means allowing a 10% variation in callback time. The window is centered on callback_time so the total number of calls within a given interval should not be significantly affected by adding jitter.

If the callback runs for longer than callback_time milliseconds, subsequent invocations will be skipped to get back on schedule.

```python
start``` must be called after the `PeriodicCallback` is created.

Changed in version 5.0: The `io_loop` argument (deprecated since version 4.1) has been removed.

Changed in version 5.1: The jitter argument is added.

Changed in version 6.2: If the callback is a coroutine, and a callback runs for longer than callback_time, subsequent invocations will be skipped. Previously this was only true for regular functions, not coroutines, which were “fire-and-forget” for `PeriodicCallback`.

The `callback_time` argument now accepts `datetime.timedelta` objects, in addition to the previous numeric milliseconds.

```python
start() → None
```
Starts the timer.

```python
stop() → None
```
Stops the timer.

```python
is_running() → bool
```
Returns True if this `PeriodicCallback` has been started.

New in version 4.1.

6.4.2 tornado.iostream — Convenient wrappers for non-blocking sockets

Utility classes to write to and read from non-blocking files and sockets.

Contents:

- **BaseIOStream**: Generic interface for reading and writing.
- **IOStream**: Implementation of BaseIOStream using non-blocking sockets.
- **SSLIOStream**: SSL-aware version of IOStream.
- **PipeIOStream**: Pipe-based IOStream implementation.

**Base class**

```python
class tornado.iostream.BaseIOStream(max_buffer_size: Optional[int] = None, read_chunk_size:
Optional[int] = None, max_write_buffer_size: Optional[int] = None)
```
A utility class to write to and read from a non-blocking file or socket.

We support a non-blocking `write()` and a family of `read_*()` methods. When the operation completes, the `Awaitable` will resolve with the data read (or None for `write()`). All outstanding `Awaitables` will resolve with a `StreamClosedError` when the stream is closed; `BaseIOStream.set_close_callback` can also be used to be notified of a closed stream.

When a stream is closed due to an error, the IOStream’s `error` attribute contains the exception object.
Subclasses must implement `fileno`, `close_fd`, `write_to_fd`, `read_from_fd`, and optionally `get_fd_error`. 

*BaseIOStream* constructor.

**Parameters**

- **`max_buffer_size`** – Maximum amount of incoming data to buffer; defaults to 100MB.
- **`read_chunk_size`** – Amount of data to read at one time from the underlying transport; defaults to 64KB.
- **`max_write_buffer_size`** – Amount of outgoing data to buffer; defaults to unlimited.

Changed in version 4.0: Add the `max_write_buffer_size` parameter. Changed default `read_chunk_size` to 64KB. 

Changed in version 5.0: The `io_loop` argument (deprecated since version 4.1) has been removed.

**Main interface**

*BaseIOStream.write*(data: `Union[bytes, memoryview]`) → `Future[None]`

Asynchronously write the given data to this stream.

This method returns a `Future` that resolves (with a result of `None`) when the write has been completed.

The data argument may be of type `bytes` or `memoryview`.

Changed in version 4.0: Now returns a `Future` if no callback is given.

Changed in version 4.5: Added support for `memoryview` arguments.

Changed in version 6.0: The callback argument was removed. Use the returned `Future` instead.

*BaseIOStream.read_bytes*(num_bytes: `int`, partial: `bool = False`) → `Awaitable[bytes]`

Asynchronously read a number of bytes.

If `partial` is true, data is returned as soon as we have any bytes to return (but never more than `num_bytes`)

Changed in version 4.0: Added the `partial` argument. The callback argument is now optional and a `Future` will be returned if it is omitted.

Changed in version 6.0: The `callback` and `streaming_callback` arguments have been removed. Use the returned `Future` (and `partial=True` for `streaming_callback`) instead.

*BaseIOStream.read_into*(buf: `bytearray`, partial: `bool = False`) → `Awaitable[int]`

Asynchronously read a number of bytes.

buf must be a writable buffer into which data will be read.

If `partial` is true, the callback is run as soon as any bytes have been read. Otherwise, it is run when the buf has been entirely filled with read data.

New in version 5.0.

Changed in version 6.0: The `callback` argument was removed. Use the returned `Future` instead.

*BaseIOStream.read_until*(delimiter: `bytes`, max_bytes: `Optional[int] = None`) → `Awaitable[bytes]`

Asynchronously read until we have found the given delimiter.

The result includes all the data read including the delimiter.

If `max_bytes` is not `None`, the connection will be closed if more than `max_bytes` bytes have been read and the delimiter is not found.
Changed in version 4.0: Added the `max_bytes` argument. The `callback` argument is now optional and a `Future` will be returned if it is omitted.

Changed in version 6.0: The `callback` argument was removed. Use the returned `Future` instead.

```
BaseIOStream.read_until_regex(regex: bytes, max_bytes: Optional[int] = None) -> Awaitable[bytes]
```

Asynchronously read until we have matched the given regex.

The result includes the data that matches the regex and anything that came before it.

If `max_bytes` is not None, the connection will be closed if more than `max_bytes` bytes have been read and the regex is not satisfied.

Changed in version 4.0: Added the `max_bytes` argument. The `callback` argument is now optional and a `Future` will be returned if it is omitted.

Changed in version 6.0: The `callback` argument was removed. Use the returned `Future` instead.

```
BaseIOStream.read_until_close() -> Awaitable[bytes]
```

Asynchronously reads all data from the socket until it is closed.

This will buffer all available data until `max_buffer_size` is reached. If flow control or cancellation are desired, use a loop with `read_bytes(partial=True)` instead.

Changed in version 4.0: The `callback` argument is now optional and a `Future` will be returned if it is omitted.

Changed in version 6.0: The `callback` and `streaming_callback` arguments have been removed. Use the returned `Future` (and `read_bytes` with `partial=True` for `streaming_callback`) instead.

```
BaseIOStream.close(exc_info: Union[None, bool, BaseException, Tuple[Optional[Type[BaseException]], Optional[BaseException], Optional[TracebackType]]] = False) -> None
```

Close this stream.

If `exc_info` is true, set the `error` attribute to the current exception from `sys.exc_info` (or if `exc_info` is a tuple, use that instead of `sys.exc_info`).

```
BaseIOStream.set_close_callback(callback: Optional[Callable[[], None]]) -> None
```

Call the given callback when the stream is closed.

This mostly is not necessary for applications that use the `Future` interface; all outstanding Futures will resolve with a `StreamClosedError` when the stream is closed. However, it is still useful as a way to signal that the stream has been closed while no other read or write is in progress.

Unlike other callback-based interfaces, `set_close_callback` was not removed in Tornado 6.0.

```
BaseIOStream.closed() -> bool
```

Returns `True` if the stream has been closed.

```
BaseIOStream.reading() -> bool
```

Returns `True` if we are currently reading from the stream.

```
BaseIOStream.writing() -> bool
```

Returns `True` if we are currently writing to the stream.

```
BaseIOStream.set_nodelay(value: bool) -> None
```

Sets the no-delay flag for this stream.

By default, data written to TCP streams may be held for a time to make the most efficient use of bandwidth (according to Nagle’s algorithm). The no-delay flag requests that data be written as soon as possible, even if doing so would consume additional bandwidth.

This flag is currently defined only for TCP-based `IOLoops`. 

6.4. Asynchronous networking
New in version 3.1.

Methods for subclasses

BaseIOStream.fileno() \(\rightarrow\) Union[int, _Selectable]
Returns the file descriptor for this stream.

BaseIOStream.close_fd() \(\rightarrow\) None
Closes the file underlying this stream.

close_fd is called by BaseIOStream and should not be called elsewhere; other users should call close instead.

BaseIOStream.write_to_fd(data: memoryview) \(\rightarrow\) int
Attempts to write data to the underlying file.

Returns the number of bytes written.

BaseIOStream.read_from_fd(buf: Union[bytearray, memoryview]) \(\rightarrow\) Optional[int]
Attempts to read from the underlying file.

Reads up to len(buf) bytes, storing them in the buffer. Returns the number of bytes read. Returns None if there was nothing to read (the socket returned EWOULDBLOCK or equivalent), and zero on EOF.

Changed in version 5.0: Interface redesigned to take a buffer and return a number of bytes instead of a freshly-allocated object.

BaseIOStream.get_fd_error() \(\rightarrow\) Optional[Exception]
Returns information about any error on the underlying file.

This method is called after the IOLoop has signaled an error on the file descriptor, and should return an Exception (such as socket.error with additional information, or None if no such information is available.

Implementations

class tornado.iostream.IOStream(socket: socket, *args: Any, **kwargs: Any)
Socket-based IOStream implementation.

This class supports the read and write methods from BaseIOStream plus a connect method.

The socket parameter may either be connected or unconnected. For server operations the socket is the result of calling socket.accept. For client operations the socket is created with socket.socket, and may either be connected before passing it to the IOStream or connected with IOStream.connect.

A very simple (and broken) HTTP client using this class:

```python
import socket
import tornado

async def main():
    s = socket.socket(socket.AF_INET, socket.SOCK_STREAM, 0)
    stream = tornado.iostream.IOStream(s)
    await stream.connect(("friendfeed.com", 80))
    await stream.write(b"GET / HTTP/1.0\r\nHost: friendfeed.com\r\n\n")
    header_data = await stream.read_until(b"\r\n")
    headers = {}
    for line in header_data.split(b"\r\n"):
        # (continues on next page)
```
connect(address: Any, server_hostname: Optional[str] = None) → Future[_IOStreamType]

Connects the socket to a remote address without blocking.

May only be called if the socket passed to the constructor was not previously connected. The address parameter is in the same format as for socket.connect for the type of socket passed to the IOStream constructor, e.g. an (ip, port) tuple. Hostnames are accepted here, but will be resolved synchronously and block the IOLoop. If you have a hostname instead of an IP address, the TCPClient class is recommended instead of calling this method directly. TCPClient will do asynchronous DNS resolution and handle both IPv4 and IPv6.

If callback is specified, it will be called with no arguments when the connection is completed; if not this method returns a Future (whose result after a successful connection will be the stream itself).

In SSL mode, the server_hostname parameter will be used for certificate validation (unless disabled in the ssl_options) and SNI (if supported; requires Python 2.7.9+).

Note that it is safe to call IOStream.write while the connection is pending, in which case the data will be written as soon as the connection is ready. Calling IOStream read methods before the socket is connected works on some platforms but is non-portable.

Changed in version 4.0: If no callback is given, returns a Future.

Changed in version 4.2: SSL certificates are validated by default; pass ssl_options=dict(cert_reqs=ssl.CERT_NONE) or a suitably-configured ssl.SSLContext to the SSLIOStream constructor to disable.

Changed in version 6.0: The callback argument was removed. Use the returned Future instead.

start_tls(server_side: bool, ssl_options: Optional[Union[Dict[str, Any], SSLContext]] = None, server_hostname: Optional[str] = None) → Awaitable[SSLIOStream]

Convert this IOStream to an SSLIOStream.

This enables protocols that begin in clear-text mode and switch to SSL after some initial negotiation (such as the STARTTLS extension to SMTP and IMAP).

This method cannot be used if there are outstanding reads or writes on the stream, or if there is any data in the IOSStream’s buffer (data in the operating system’s socket buffer is allowed). This means it must generally be used immediately after reading or writing the last clear-text data. It can also be used immediately after connecting, before any reads or writes.

The ssl_options argument may be either an ssl.SSLContext object or a dictionary of keyword arguments for the ssl.wrap_socket function. The server_hostname argument will be used for certificate validation unless disabled in the ssl_options.

This method returns a Future whose result is the new SSLIOStream. After this method has been called, any other operation on the original stream is undefined.

If a close callback is defined on this stream, it will be transferred to the new stream.
New in version 4.0.

Changed in version 4.2: SSL certificates are validated by default; pass `ssl_options=dict(cert_reqs=ssl.CERT_NONE)` or a suitably-configured `ssl.SSLContext` to disable.

class tornado.iostream.SSLIOStream(*args: Any, **kwargs: Any)
A utility class to write to and read from a non-blocking SSL socket.

If the socket passed to the constructor is already connected, it should be wrapped with:

```python
ssl.wrap_socket(sock, do_handshake_on_connect=False, **kwargs)
```

before constructing the `SSLIOStream`. Unconnected sockets will be wrapped when `IOStream.connect` is finished.

The `ssl_options` keyword argument may either be an `ssl.SSLContext` object or a dictionary of keywords arguments for `ssl.wrap_socket`

`wait_for_handshake()` → `Future[SSLIOStream]`

Wait for the initial SSL handshake to complete.

If a callback is given, it will be called with no arguments once the handshake is complete; otherwise this method returns a `Future` which will resolve to the stream itself after the handshake is complete.

Once the handshake is complete, information such as the peer’s certificate and NPN/ALPN selections may be accessed on `self.socket`.

This method is intended for use on server-side streams or after using `IOStream.start_tls`; it should not be used with `IOStream.connect` (which already waits for the handshake to complete). It may only be called once per stream.

New in version 4.2.

Changed in version 6.0: The callback argument was removed. Use the returned `Future` instead.

class tornado.iostream.PipeIOStream(fd: int, *args: Any, **kwargs: Any)
Pipe-based `IOStream` implementation.

The constructor takes an integer file descriptor (such as one returned by `os.pipe`) rather than an open file object. Pipes are generally one-way, so a `PipeIOStream` can be used for reading or writing but not both.

`PipeIOStream` is only available on Unix-based platforms.

**Exceptions**

exception tornado.iostream.StreamBufferFullError
Exception raised by `IOStream` methods when the buffer is full.

exception tornado.iostream.StreamClosedError(real_error: Optional[BaseException] = None)
Exception raised by `IOStream` methods when the stream is closed.

Note that the close callback is scheduled to run after other callbacks on the stream (to allow for buffered data to be processed), so you may see this error before you see the close callback.

The `real_error` attribute contains the underlying error that caused the stream to close (if any).

Changed in version 4.3: Added the `real_error` attribute.
exception tornado.iostream.UnsatisfiableReadError
    Exception raised when a read cannot be satisfied.
    Raised by read_until and read_until_regex with a max_bytes argument.

6.4.3 tornado.netutil — Miscellaneous network utilities

Miscellaneous network utility code.

tornado.netutil.bind_sockets(port: int, address: Optional[str] = None, family: AddressFamily =
    AddressFamily.AF_UNSPEC, backlog: int = 128, flags: Optional[int] = None,
    reuse_port: bool = False) → List[socket]

Creates listening sockets bound to the given port and address.

Returns a list of socket objects (multiple sockets are returned if the given address maps to multiple IP addresses,
which is most common for mixed IPv4 and IPv6 use).

Address may be either an IP address or hostname. If it’s a hostname, the server will listen on all IP addresses
associated with the name. Address may be an empty string or None to listen on all available interfaces. Family
may be set to either socket.AF_INET or socket.AF_INET6 to restrict to IPv4 or IPv6 addresses, otherwise
both will be used if available.

The backlog argument has the same meaning as for socket.listen().

flags is a bitmask of AI_* flags to getaddrinfo, like socket.AI_PASSIVE | socket.AI_NUMERICHOST.

reuse_port option sets SO_REUSEPORT option for every socket in the list. If your platform doesn’t support this
option ValueError will be raised.

tornado.netutil.bind_unix_socket(file: str, mode: int = 384, backlog: int = 128) → socket

Creates a listening unix socket.

If a socket with the given name already exists, it will be deleted. If any other file with that name exists, an
exception will be raised.

Returns a socket object (not a list of socket objects like bind_sockets)

tornado.netutil.add_accept_handler(sock: socket, callback: Callable[[socket, Any], None]) → Callable[[],
    None]

Adds an IOLoop event handler to accept new connections on sock.

When a connection is accepted, callback(connection, address) will be run (connection is a socket ob-
ject, and address is the address of the other end of the connection). Note that this signature is different from
the callback(fd, events) signature used for IOLoop handlers.

A callable is returned which, when called, will remove the IOLoop event handler and stop processing further
incoming connections.

Changed in version 5.0: The io_loop argument (deprecated since version 4.1) has been removed.

Changed in version 5.0: A callable is returned (None was returned before).

tornado.netutil.is_valid_ip(ip: str) → bool

Returns True if the given string is a well-formed IP address.

Supports IPv4 and IPv6.
class tornado.netutil.Resolver(*args: Any, **kwargs: Any)
Configurable asynchronous DNS resolver interface.

By default, a blocking implementation is used (which simply calls `socket.getaddrinfo`). An alternative implementation can be chosen with the `Resolver.configure` class method:

```python
Resolver.configure('tornado.netutil.ThreadedResolver')
```

The implementations of this interface included with Tornado are

- `tornado.netutil.DefaultLoopResolver`
- `tornado.netutil.DefaultExecutorResolver` (deprecated)
- `tornado.netutil.BlockingResolver` (deprecated)
- `tornado.netutil.ThreadedResolver` (deprecated)
- `tornado.netutil.OverrideResolver`
- `tornado.platform.twisted.TwistedResolver` (deprecated)
- `tornado.platform.caresresolver.CaresResolver` (deprecated)

Changed in version 5.0: The default implementation has changed from `BlockingResolver` to `DefaultExecutorResolver`.

Changed in version 6.2: The default implementation has changed from `DefaultExecutorResolver` to `DefaultLoopResolver`.

**resolve**(host: str, port: int, family: AddressFamily = AddressFamily.AF_UNSPEC) → Awaitable[List[Tuple[int, Any]]]

Resolves an address.

The `host` argument is a string which may be a hostname or a literal IP address.

Returns a `Future` whose result is a list of (family, address) pairs, where address is a tuple suitable to pass to `socket.connect` (i.e. a `(host, port)` pair for IPv4; additional fields may be present for IPv6). If a `callback` is passed, it will be run with the result as an argument when it is complete.

Raises

- `IOError` – if the address cannot be resolved.

Changed in version 4.4: Standardized all implementations to raise `IOError`.

Changed in version 6.0: The `callback` argument was removed. Use the returned awaitable object instead.

**close**() → None

Closes the `Resolver`, freeing any resources used.

New in version 3.1.

class tornado.netutil.DefaultExecutorResolver(*args: Any, **kwargs: Any)

Resolver implementation using `IOLoop.run_in_executor`.

New in version 5.0.

Deprecated since version 6.2: Use `DefaultLoopResolver` instead.

class tornado.netutil.DefaultLoopResolver(*args: Any, **kwargs: Any)

Resolver implementation using `asyncio.loop.getaddrinfo`. 
class tornado.netutil.ExecutorResolver(*args: Any, **kwargs: Any)
    Resolver implementation using a concurrent.futures.Executor.
    Use this instead of ThreadedResolver when you require additional control over the executor being used.
    The executor will be shut down when the resolver is closed unless close_resolver=False; use this if you want to reuse the same executor elsewhere.
    Changed in version 5.0: The io_loop argument (deprecated since version 4.1) has been removed.
    Deprecated since version 5.0: The default Resolver now uses asyncio.loop.getaddrinfo; use that instead of this class.

class tornado.netutil.BlockingResolver(*args: Any, **kwargs: Any)
    Default Resolver implementation, using socket.getaddrinfo.
    The IOLoop will be blocked during the resolution, although the callback will not be run until the next IOLoop iteration.
    Deprecated since version 5.0: The default Resolver now uses IOLoop.run_in_executor; use that instead of this class.

class tornado.netutil.ThreadedResolver(*args: Any, **kwargs: Any)
    Multithreaded non-blocking Resolver implementation.
    Requires the concurrent.futures package to be installed (available in the standard library since Python 3.2, installable with pip install futures in older versions).
    The thread pool size can be configured with:

    Resolver.configure('tornado.netutil.ThreadedResolver',
                       num_threads=10)

    Changed in version 3.1: All ThreadedResolvers share a single thread pool, whose size is set by the first one to be created.
    Deprecated since version 5.0: The default Resolver now uses IOLoop.run_in_executor; use that instead of this class.

class tornado.netutil.OverrideResolver(*args: Any, **kwargs: Any)
    Wraps a resolver with a mapping of overrides.
    This can be used to make local DNS changes (e.g. for testing) without modifying system-wide settings.
    The mapping can be in three formats:

    {
        # Hostname to host or ip
        "example.com": "127.0.1.1",

        # Host+port to host+port
        ("login.example.com", 443): ("localhost", 1443),

        # Host+port+address family to host+port
        ("login.example.com", 443, socket.AF_INET6): (":1", 1443),
    }

    Changed in version 5.0: Added support for host-port-family triplets.
tornado.netutil.ssl_options_to_context(ssl_options: Union[Dict[str, Any], SSLContext], server_side: Optional[bool] = None) → SSLContext

Try to convert an ssl_options dictionary to an SSLContext object.

The ssl_options dictionary contains keywords to be passed to ssl.wrap_socket. In Python 2.7.9+, ssl. SSLContext objects can be used instead. This function converts the dict form to its SSLContext equivalent, and may be used when a component which accepts both forms needs to upgrade to the SSLContext version to use features like SNI or NPN.

Changed in version 6.2: Added server_side argument. Omitting this argument will result in a DeprecationWarning on Python 3.10.

```python
tornado.netutil.ssl_wrap_socket(socket: socket, ssl_options: Union[Dict[str, Any], SSLContext], server_hostname: Optional[str] = None, server_side: Optional[bool] = None, **kwargs: Any) → SSLSocket
```

Returns an ssl.SSLSocket wrapping the given socket.

ssl_options may be either an ssl.SSLContext object or a dictionary (as accepted by ssl_options_to_context). Additional keyword arguments are passed to wrap_socket (either the SSLContext method or the ssl module function as appropriate).

Changed in version 6.2: Added server_side argument. Omitting this argument will result in a DeprecationWarning on Python 3.10.

### 6.4.4 tornado.tcpclient — IOStream connection factory

A non-blocking TCP connection factory.

```python
class tornado.tcpclient.TCPClient(resolver: Optional[Resolver] = None)
```

A non-blocking TCP connection factory.

Changed in version 5.0: The io_loop argument (deprecated since version 4.1) has been removed.

```python
coroutine connect(host: str, port: int, af: AddressFamily = AddressFamily.AF_UNSPEC, ssl_options: Optional[Union[Dict[str, Any], SSLContext]] = None, max_buffer_size: Optional[int] = None, source_ip: Optional[str] = None, source_port: Optional[int] = None, timeout: Optional[Union[float, timedelta]] = None) → IOStream
```

Connect to the given host and port.

Asynchronously returns an IOStream (or SSLIOStream if ssl_options is not None).

Using the source_ip kwarg, one can specify the source IP address to use when establishing the connection. In case the user needs to resolve and use a specific interface, it has to be handled outside of Tornado as this depends very much on the platform.

Raises TimeoutError if the input future does not complete before timeout, which may be specified in any form allowed by IOLoop.add_timeout (i.e. a datetime.timedelta or an absolute time relative to IOLoop.time)

Similarly, when the user requires a certain source port, it can be specified using the source_port arg.

Changed in version 4.5: Added the source_ip and source_port arguments.

Changed in version 5.0: Added the timeout argument.
6.4.5 **tornado.tcpserver — Basic Iostream-based TCP server**

A non-blocking, single-threaded TCP server.

```python
class tornado.tcpserver.TCPServer(ssl_options: Optional[Union[Dict[str, Any], SSLContext]] = None,
max_buffer_size: Optional[int] = None, read_chunk_size: Optional[int] = None)
```

A non-blocking, single-threaded TCP server.

To use TCPServer, define a subclass which overrides the `handle_stream` method. For example, a simple echo server could be defined like this:

```python
from tornado.tcpserver import TCPServer
from tornado.iostream import StreamClosedError

class EchoServer(TCPServer):
    async def handle_stream(self, stream, address):
        while True:
            try:
                data = await stream.read_until(b'

) await
                stream.write(data)
            except StreamClosedError:
                break
```

To make this server serve SSL traffic, send the `ssl_options` keyword argument with an `ssl.SSLContext` object. For compatibility with older versions of Python `ssl_options` may also be a dictionary of keyword arguments for the `ssl.wrap_socket` method:

```python
ssl_ctx = ssl.create_default_context(ssl.Purpose.CLIENT_AUTH)
ssl_ctx.load_cert_chain(os.path.join(data_dir, "mydomain.crt"),
                        os.path.join(data_dir, "mydomain.key"))
TCPServer(ssl_options=ssl_ctx)
```

The `TCPServer` initialization follows one of three patterns:

1. **listen**: single-process:

   ```python
   async def main():
       server = TCPServer()
       server.listen(8888)
       await asyncio.Event.wait()
   asyncio.run(main())
   ```

   While this example does not create multiple processes on its own, when the `reuse_port=True` argument is passed to `listen()` you can run the program multiple times to create a multi-process service.

2. **add_sockets**: multi-process:

   ```python
   sockets = bind_sockets(8888)
   tornado.process.fork_processes(0)
   async def post_fork_main():
       server = TCPServer()
       server.add_sockets(sockets)
       await asyncio.Event().wait()
   asyncio.run(post_fork_main())
   ```

---

6.4. Asynchronous networking 117
The `add_sockets` interface is more complicated, but it can be used with `tornado.process.fork_processes` to run a multi-process service with all worker processes forked from a single parent. `add_sockets` can also be used in single-process servers if you want to create your listening sockets in some way other than `bind_sockets`.

Note that when using this pattern, nothing that touches the event loop can be run before `fork_processes`.

3. **bind/start**: simple deprecated multi-process:

```python
server = TCPServer()
server.bind(8888)
server.start(0)  # Forks multiple sub-processes
IOLoop.current().start()
```

This pattern is deprecated because it requires interfaces in the `asyncio` module that have been deprecated since Python 3.10. Support for creating multiple processes in the `start` method will be removed in a future version of Tornado.

New in version 3.1: The `max_buffer_size` argument.

Changed in version 5.0: The `io_loop` argument has been removed.

**listen**

```python
listen(port: int, address: Optional[str] = None, family: AddressFamily = AddressFamily.AF_UNSPEC,
      backlog: int = 128, flags: Optional[int] = None, reuse_port: bool = False) → None
```

Starts accepting connections on the given port.

This method may be called more than once to listen on multiple ports. `listen` takes effect immediately; it is not necessary to call `TCPServer.start` afterwards. It is, however, necessary to start the event loop if it is not already running.

All arguments have the same meaning as in `tornado.netutil.bind_sockets`.

Changed in version 6.2: Added `family`, `backlog`, `flags`, and `reuse_port` arguments to match `tornado.netutil.bind_sockets`.

**add_sockets**

```python
add_sockets(sockets: Iterable[socket]) → None
```

Makes this server start accepting connections on the given sockets.

The `sockets` parameter is a list of socket objects such as those returned by `bind_sockets`. `add_sockets` is typically used in combination with that method and `tornado.process.fork_processes` to provide greater control over the initialization of a multi-process server.

**add_socket**

```python
add_socket(socket: socket) → None
```

Singular version of `add_sockets`. Takes a single socket object.

**bind**

```python
bind(port: int, address: Optional[str] = None, family: AddressFamily = AddressFamily.AF_UNSPEC,
     backlog: int = 128, flags: Optional[int] = None, reuse_port: bool = False) → None
```

Binds this server to the given port on the given address.

To start the server, call `start`. If you want to run this server in a single process, you can call `listen` as a shortcut to the sequence of `bind` and `start` calls.

Address may be either an IP address or hostname. If it’s a hostname, the server will listen on all IP addresses associated with the name. Address may be an empty string or None to listen on all available interfaces. Family may be set to either `socket.AF_INET` or `socket.AF_INET6` to restrict to IPv4 or IPv6 addresses, otherwise both will be used if available.

The `backlog` argument has the same meaning as for `socket.listen`. The `reuse_port` argument has the same meaning as for `bind_sockets`.

This method may be called multiple times prior to `start` to listen on multiple ports or interfaces.
Changed in version 4.4: Added the `reuse_port` argument.

Changed in version 6.2: Added the `flags` argument to match `bind_sockets`.

Deprecated since version 6.2: Use either `listen()` or `add_sockets()` instead of `bind()` and `start()`.

**start** *(num_processes: Optional[int] = 1, max_restarts: Optional[int] = None) → None*

Starts this server in the `IOLoop`.

By default, we run the server in this process and do not fork any additional child process.

If `num_processes` is `None` or <= 0, we detect the number of cores available on this machine and fork that number of child processes. If `num_processes` is given and > 1, we fork that specific number of sub-processes.

Since we use processes and not threads, there is no shared memory between any server code.

Note that multiple processes are not compatible with the autoreload module (or the `autoreload=True` option to `tornado.web.Application` which defaults to True when `debug=True`). When using multiple processes, no `IOLoops` can be created or referenced until after the call to `TCPServer.start(n)`.

Values of `num_processes` other than 1 are not supported on Windows.

The `max_restarts` argument is passed to `fork_processes`.

Changed in version 6.0: Added `max_restarts` argument.

Deprecated since version 6.2: Use either `listen()` or `add_sockets()` instead of `bind()` and `start()`.

**stop() → None**

Stops listening for new connections.

Requests currently in progress may still continue after the server is stopped.

**handle_stream**(stream: IOStream, address: tuple) → Optional[Awaitable[None]]

Override to handle a new `IOLstream` from an incoming connection.

This method may be a coroutine; if so any exceptions it raises asynchronously will be logged. Accepting of incoming connections will not be blocked by this coroutine.

If this `TCPServer` is configured for SSL, `handle_stream` may be called before the SSL handshake has completed. Use `SSLIOStream.wait_for_handshake` if you need to verify the client's certificate or use NPN/ALPN.

Changed in version 4.2: Added the option for this method to be a coroutine.

### 6.5 Coroutines and concurrency

#### 6.5.1 tornado.gen — Generator-based coroutines

tornado.gen implements generator-based coroutines.

Note: The “decorator and generator” approach in this module is a precursor to native coroutines (using `async def` and `await`) which were introduced in Python 3.5. Applications that do not require compatibility with older versions of Python should use native coroutines instead. Some parts of this module are still useful with native coroutines, notably `multi`, `sleep`, `WaitIterator`, and `with_timeout`. Some of these functions have counterparts in the `asyncio` module which may be used as well, although the two may not necessarily be 100% compatible.
Coroutines provide an easier way to work in an asynchronous environment than chaining callbacks. Code using coroutines is technically asynchronous, but it is written as a single generator instead of a collection of separate functions.

For example, here’s a coroutine-based handler:

```python
class GenAsyncHandler(RequestHandler):
    @gen.coroutine
    def get(self):
        http_client = AsyncHTTPClient()
        response = yield http_client.fetch("http://example.com")
        do_something_with_response(response)
        self.render("template.html")
```

Asynchronous functions in Tornado return an `Awaitable` or `Future`; yielding this object returns its result.

You can also yield a list or dict of other yieldable objects, which will be started at the same time and run in parallel; a list or dict of results will be returned when they are all finished:

```python
@gen.coroutine
def get(self):
    http_client = AsyncHTTPClient()
    response1, response2 = yield [http_client.fetch(url1), http_client.fetch(url2)]
    response_dict = yield dict(response3=http_client.fetch(url3), response4=http_client.fetch(url4))
    response3 = response_dict['response3']
    response4 = response_dict['response4']
```

If `tornado.platform.twisted` is imported, it is also possible to yield Twisted’s `Deferred` objects. See the `convert_yielded` function to extend this mechanism.

Changed in version 3.2: Dict support added.

Changed in version 4.1: Support added for yielding asyncio Futures and Twisted Deferreds via `singledispatch`.

### Decorators

`tornado.gen.coroutine(func: Callable[..., Generator[Any, Any, _T]]) → Callable[...], Future[_T]]`

`tornado.gen.coroutine(func: Callable[..., _T]) → Callable[...], Future[_T]]`

Decorator for asynchronous generators.

For compatibility with older versions of Python, coroutines may also “return” by raising the special exception `Return(value)`.

Functions with this decorator return a `Future`.

**Warning:** When exceptions occur inside a coroutine, the exception information will be stored in the `Future` object. You must examine the result of the `Future` object, or the exception may go unnoticed by your code. This means yielding the function if called from another coroutine, using something like `IOLoop.run_sync` for top-level calls, or passing the `Future` to `IOLoop.add_future`.

Changed in version 6.0: The callback argument was removed. Use the returned awaitable object instead.
exception tornado.gen.Return(value: Optional[Any] = None)

Special exception to return a value from a coroutine.

If this exception is raised, its value argument is used as the result of the coroutine:

```python
@gen.coroutine
def fetch_json(url):
    response = yield AsyncHTTPClient().fetch(url)
    raise gen.Return(json_decode(response.body))
```

In Python 3.3, this exception is no longer necessary: the return statement can be used directly to return a value (previously yield and return with a value could not be combined in the same function).

By analogy with the return statement, the value argument is optional, but it is never necessary to raise gen. Return(). The return statement can be used with no arguments instead.

Utility functions

tornado.gen.with_timeout(timeout: Union[float, datetime.timedelta], future: Yieldable, quiet_exceptions: Union[Type[Exception], Tuple[Type[Exception], ...]] = ())

Wraps a Future (or other yieldable object) in a timeout.

Raises tornado.util.TimeoutError if the input future does not complete before timeout, which may be specified in any form allowed by IOLoop.add_timeout (i.e. a datetime.timedelta or an absolute time relative to IOLoop.time)

If the wrapped Future fails after it has timed out, the exception will be logged unless it is either of a type contained in quiet_exceptions (which may be an exception type or a sequence of types), or an asyncio.CancelledError.

The wrapped Future is not canceled when the timeout expires, permitting it to be reused. asyncio.wait_for is similar to this function but it does cancel the wrapped Future on timeout.

New in version 4.0.

Changed in version 4.1: Added the quiet_exceptions argument and the logging of unhandled exceptions.

Changed in version 4.4: Added support for yieldable objects other than Future.

Changed in version 6.0.3: asyncio.CancelledError is now always considered “quiet”.

Changed in version 6.2: tornado.util.TimeoutError is now an alias to asyncio.TimeoutError.

tornado.gen.sleep(duration: float) → Future[None]

Return a Future that resolves after the given number of seconds.

When used with yield in a coroutine, this is a non-blocking analogue to time.sleep (which should not be used in coroutines because it is blocking):

```python
yield gen.sleep(0.5)
```

Note that calling this function on its own does nothing; you must wait on the Future it returns (usually by yielding it).

New in version 4.1.

class tornado.gen.WaitIterator(*args: Future, **kwargs: Future)

Provides an iterator to yield the results of awaitables as they finish.

Yielding a set of awaitables like this:
results = yield [awaitable1, awaitable2]

pauses the coroutine until both awaitable1 and awaitable2 return, and then restarts the coroutine with the results of both awaitables. If either awaitable raises an exception, the expression will raise that exception and all the results will be lost.

If you need to get the result of each awaitable as soon as possible, or if you need the result of some awaitables even if others produce errors, you can use WaitIterator:

```python
wait_iterator = gen.WaitIterator(awaitable1, awaitable2)
while not wait_iterator.done():
    try:
        result = yield wait_iterator.next()
    except Exception as e:
        print("Error {} from {}".format(e, wait_iterator.current_future))
    else:
        print("Result {} received from {} at {}".format(
            result, wait_iterator.current_future,
            wait_iterator.current_index))
```

Because results are returned as soon as they are available the output from the iterator will not be in the same order as the input arguments. If you need to know which future produced the current result, you can use the attributes WaitIterator.current_future, or WaitIterator.current_index to get the index of the awaitable from the input list. (If keyword arguments were used in the construction of the WaitIterator, current_index will use the corresponding keyword).

On Python 3.5, WaitIterator implements the async iterator protocol, so it can be used with the async for statement (note that in this version the entire iteration is aborted if any value raises an exception, while the previous example can continue past individual errors):

```python
async for result in gen.WaitIterator(future1, future2):
    print("Result {} received from {} at {}".format(
        result, wait_iterator.current_future,
        wait_iterator.current_index))
```

New in version 4.1.

Changed in version 4.3: Added async for support in Python 3.5.

done() → bool

Returns True if this iterator has no more results.

next() → Future

Returns a Future that will yield the next available result.

Note that this Future will not be the same object as any of the inputs.

tornado.gen.multi(Union[List[Yieldable], Dict[Any, Yieldable]], quiet Exceptions: Union[Type[Exception], Tuple[Type[Exception], ...]] = ())

Runs multiple asynchronous operations in parallel.

children may either be a list or a dict whose values are yieldable objects. multi() returns a new yieldable object that resolves to a parallel structure containing their results. If children is a list, the result is a list of results in the same order; if it is a dict, the result is a dict with the same keys.

That is, results = yield multi(list_of_futures) is equivalent to:
results = []
for future in list_of_futures:
    results.append(yield future)

If any children raise exceptions, multi() will raise the first one. All others will be logged, unless they are of

types contained in the quiet_exceptions argument.

In a yield-based coroutine, it is not normally necessary to call this function directly, since the coroutine runner

do it automatically when a list or dict is yielded. However, it is necessary in await-based coroutines, or to

pass the quiet_exceptions argument.

This function is available under the names multi() and Multi() for historical reasons.

Cancelling a Future returned by multi() does not cancel its children. asyncio.gather is similar to multi(),
but it does cancel its children.

Changed in version 4.2: If multiple yieldables fail, any exceptions after the first (which is raised) will be logged.
Added the quiet_exceptions argument to suppress this logging for selected exception types.

Changed in version 4.3: Replaced the class Multi and the function multi_future with a unified function
multi. Added support for yieldables other than YieldPoint and Future.

tornado.gen.multi_future(Union[List[Yieldable], Dict[Any, Yieldable]], quiet_exceptions:
    Union[Type[Exception], Tuple[Type[Exception], ...]] = ())

Wait for multiple asynchronous futures in parallel.

Since Tornado 6.0, this function is exactly the same as multi.

New in version 4.0.

Changed in version 4.2: If multiple Futures fail, any exceptions after the first (which is raised) will be logged.
Added the quiet_exceptions argument to suppress this logging for selected exception types.

Deprecated since version 4.3: Use multi instead.

tornado.gen.convert_yielded(yielded: Union[None, Awaitable, List[Awaitable], Dict[Any, Awaitable],
    Future]) → Future

Convert a yielded object into a Future.

The default implementation accepts lists, dictionaries, and Futures. This has the side effect of starting any corou-
tines that did not start themselves, similar to asyncio.ensure_future.

If the singledispatch library is available, this function may be extended to support additional types. For
example:

```python
@convert_yielded.register(asyncio.Future)
def _(asyncio_future):
    return tornado.platform.asyncio.to_tornado_future(asyncio_future)
```

New in version 4.1.

tornado.gen.maybe_future(x: Any) → Future

Converts x into a Future.

If x is already a Future, it is simply returned; otherwise it is wrapped in a new Future. This is suitable for use
as result = yield gen.maybe_future(f()) when you don’t know whether f() returns a Future or not.

Deprecated since version 4.3: This function only handles Futures, not other yieldable objects. Instead of
maybe_future, check for the non-future result types you expect (often just None), and yield anything unknown.
tornado.gen.is_coroutine_function(func: Any) → bool

Return whether func is a coroutine function, i.e. a function wrapped with coroutine.

New in version 4.5.

tornado.gen.moment

A special object which may be yielded to allow the IOLoop to run for one iteration.

This is not needed in normal use but it can be helpful in long-running coroutines that are likely to yield Futures that are ready instantly.

Usage: yield gen.moment

In native coroutines, the equivalent of yield gen.moment is await asyncio.sleep(0).

New in version 4.0.

Deprecated since version 4.5: yield None (or yield with no argument) is now equivalent to yield gen.moment.

6.5.2 tornado.locks – Synchronization primitives

New in version 4.2.

Coordinate coroutines with synchronization primitives analogous to those the standard library provides to threads. These classes are very similar to those provided in the standard library’s asyncio package.

**Warning:** Note that these primitives are not actually thread-safe and cannot be used in place of those from the standard library’s threading module—they are meant to coordinate Tornado coroutines in a single-threaded app, not to protect shared objects in a multithreaded app.

Condition

class tornado.locks.Condition

A condition allows one or more coroutines to wait until notified.

Like a standard threading.Condition, but does not need an underlying lock that is acquired and released.

With a Condition, coroutines can wait to be notified by other coroutines:

```python
import asyncio
from tornado import gen
from tornado.locks import Condition

condition = Condition()

async def waiter():
    print("I'll wait right here")
    await condition.wait()
    print("I'm done waiting")

async def notifier():
    print("About to notify")
    condition.notify()
```

(continues on next page)
print("Done notifying")

async def runner():
    # Wait for waiter() and notifier() in parallel
    await gen.multi([waiter(), notifier()])

asyncio.run(runner())

I'll wait right here
About to notify
Done notifying
I'm done waiting

...or a \texttt{datetime.timedelta} for a timeout relative to the current time:

\begin{verbatim}
# Wait up to 1 second.
await condition.wait(timeout=datetime.timedelta(seconds=1))
\end{verbatim}

The method returns False if there’s no notification before the deadline.

Changed in version 5.0: Previously, waiters could be notified synchronously from within \texttt{notify}. Now, the notification will always be received on the next iteration of the \texttt{IOLoop}.

\begin{verbatim}
wait(timeout: Optional[Union[float, timedelta]] = None) \to \texttt{Awaitable[bool]}
\end{verbatim}

Wait for \texttt{notify}.
Returns a \texttt{Future} that resolves \texttt{True} if the condition is notified, or \texttt{False} after a timeout.

\begin{verbatim}
notify(n: int = 1) \to \texttt{None}
\end{verbatim}

Wake \texttt{n} waiters.

\begin{verbatim}
notify_all() \to \texttt{None}
\end{verbatim}

Wake all waiters.

\textbf{Event}

\begin{verbatim}
import asyncio
from tornado import gen
from tornado.locks import Event
\end{verbatim}

6.5. Coroutines and concurrency
event = Event()

async def waiter():
    print("Waiting for event")
    await event.wait()
    print("Not waiting this time")
    await event.wait()
    print("Done")

async def setter():
    print("About to set the event")
    event.set()

async def runner():
    await gen.multi([waiter(), setter()])

asyncio.run(runner())

Waiting for event
About to set the event
Not waiting this time
Done

is_set() → bool
    Return True if the internal flag is true.

set() → None
    Set the internal flag to True. All waiters are awakened.
    Calling wait once the flag is set will not block.

clear() → None
    Reset the internal flag to False.
    Calls to wait will block until set is called.

wait(timeout: Optional[Union[float, timedelta]] = None) → Awaitable[None]
    Block until the internal flag is true.
    Returns an awaitable, which raises tornado.util.TimeoutError after a timeout.

Semaphore

class tornado.locks.Semaphore(value: int = 1)
    A lock that can be acquired a fixed number of times before blocking.

    A Semaphore manages a counter representing the number of release calls minus the number of acquire calls, plus an initial value. The acquire method blocks if necessary until it can return without making the counter negative.

    Semaphores limit access to a shared resource. To allow access for two workers at a time:
import asyncio
from tornado import gen
from tornado.locks import Semaphore

sem = Semaphore(2)

async def worker(worker_id):
    await sem.acquire()
    try:
        print("Worker %d is working" % worker_id)
        await use_some_resource()
    finally:
        print("Worker %d is done" % worker_id)
        sem.release()

async def runner():
    # Join all workers.
    await gen.multi([worker(i) for i in range(3)])

asyncio.run(runner())

Worker 0 is working
Worker 1 is working
Worker 0 is done
Worker 2 is working
Worker 1 is done
Worker 2 is done

Workers 0 and 1 are allowed to run concurrently, but worker 2 waits until the semaphore has been released once, by worker 0.

The semaphore can be used as an async context manager:

async def worker(worker_id):
    async with sem:
        print("Worker %d is working" % worker_id)
        await use_some_resource()
        # Now the semaphore has been released.
        print("Worker %d is done" % worker_id)

For compatibility with older versions of Python, acquire is a context manager, so worker could also be written as:

@gen.coroutine
def worker(worker_id):
    with (yield sem.acquire()):
        print("Worker %d is working" % worker_id)
        yield use_some_resource()
        # Now the semaphore has been released.
        print("Worker %d is done" % worker_id)

Changed in version 4.3: Added async with support in Python 3.5.
**release() → None**

Increment the counter and wake one waiter.

**acquire(timeout: Optional[Union[float, timedelta]] = None) → Awaitable[_ReleasingContextManager]**

Decrement the counter. Returns an awaitable.

Block if the counter is zero and wait for a release. The awaitable raises TimeoutError after the deadline.

---

**BoundedSemaphore**

class tornado.locks.BoundedSemaphore(value: int = 1)

A semaphore that prevents release() being called too many times.

If release would increment the semaphore’s value past the initial value, it raises ValueError. Semaphores are mostly used to guard resources with limited capacity, so a semaphore released too many times is a sign of a bug.

**release() → None**

Increment the counter and wake one waiter.

**acquire(timeout: Optional[Union[float, timedelta]] = None) → Awaitable[_ReleasingContextManager]**

Decrement the counter. Returns an awaitable.

Block if the counter is zero and wait for a release. The awaitable raises TimeoutError after the deadline.

---

**Lock**

class tornado.locks.Lock

A lock for coroutines.

A Lock begins unlocked, and acquire locks it immediately. While it is locked, a coroutine that yields acquire waits until another coroutine calls release.

Releasing an unlocked lock raises RuntimeError.

A Lock can be used as an async context manager with the async with statement:

```
>>> from tornado import locks
>>> lock = locks.Lock()

>>> async def f():
...     async with lock:
...         # Do something holding the lock.
...         pass

...     # Now the lock is released.
```

For compatibility with older versions of Python, the acquire method asynchronously returns a regular context manager:

```
>>> async def f2():
...     with (yield lock.acquire()):
...         # Do something holding the lock.
...         pass

...     # Now the lock is released.
```
Changed in version 4.3: Added `async` with support in Python 3.5.

```python
async with acquisition(timeout: Optional[Union[float, timedelta]] = None) → Awaitable[_ReleasingContextManager]
```

Attempt to lock. Returns an awaitable.

Returns an awaitable, which raises `tornado.util.TimeoutError` after a timeout.

```python
release() → None
```

Unlock.

The first coroutine in line waiting for `acquire` gets the lock.

If not locked, raise a `RuntimeError`.

### 6.5.3 tornado.queues – Queues for coroutines

New in version 4.2. Asynchronous queues for coroutines. These classes are very similar to those provided in the standard library’s `asyncio` package.

**Warning:** Unlike the standard library’s `queue` module, the classes defined here are *not* thread-safe. To use these queues from another thread, use `IOLoop.add_callback` to transfer control to the `IOLoop` thread before calling any queue methods.

#### Classes

**Queue**

```python
class tornado.queues.Queue(maxsize: int = 0)
```

Coordinate producer and consumer coroutines.

If maxsize is 0 (the default) the queue size is unbounded.

```python
import asyncio
from tornado.ioloop import IOLoop
from tornado.queues import Queue

q = Queue(maxsize=2)

async def consumer():
    async for item in q:
        try:
            print('Doing work on %s' % item)
            await asyncio.sleep(0.01)
        finally:
            q.task_done()

async def producer():
    for item in range(5):
        await q.put(item)
        print('Put %s' % item)

async def main():
```

(continues on next page)
# Start consumer without waiting (since it never finishes).
IOLoop.current().spawn_callback(consumer)

```
await producer()  # Wait for producer to put all tasks.
await q.join()     # Wait for consumer to finish all tasks.
print('Done')
```

asyncio.run(main())

Put 0
Put 1
 Doing work on 0
Put 2
 Doing work on 1
Put 3
 Doing work on 2
Put 4
 Doing work on 3
Doing work on 4
Done

In versions of Python without native coroutines (before 3.5), `consumer()` could be written as:

```
@gen.coroutine
def consumer():
    while True:
        item = yield q.get()
        try:
            print('Doing work on %s' % item)
            yield gen.sleep(0.01)
        finally:
            q.task_done()
```

Changed in version 4.3: Added `async for` support in Python 3.5.

**property maxsize:** `int`
Number of items allowed in the queue.

**qsize()** → `int`
Number of items in the queue.

**put**(`item: _T, timeout: Optional[Union[float, timedelta]] = None`) → `Future[None]`
Put an item into the queue, perhaps waiting until there is room.

Returns a Future, which raises `tornado.util.TimeoutError` after a timeout.

timeout may be a number denoting a time (on the same scale as `tornado.ioloop.IOLoop.time`, normally `time.time`), or a `datetime.timedelta` object for a deadline relative to the current time.

**put_nowait**(`item: _T`) → `None`
Put an item into the queue without blocking.

If no free slot is immediately available, raise `QueueFull`.

**get**(`timeout: Optional[Union[float, timedelta]] = None`) → `Awaitable[_T]`
Remove and return an item from the queue.
Returns an awaitable which resolves once an item is available, or raises `tornado.util.TimeoutError` after a timeout.

`timeout` may be a number denoting a time (on the same scale as `tornado.ioloop.IOLoop.time`, normally `time.time`), or a `datetime.timedelta` object for a deadline relative to the current time.

**Note:** The `timeout` argument of this method differs from that of the standard library’s `queue.Queue.get`. That method interprets numeric values as relative timeouts; this one interprets them as absolute deadlines and requires `timedelta` objects for relative timeouts (consistent with other timeouts in Tornado).

```python
get_nowait() → _T
Remove and return an item from the queue without blocking.

Return an item if one is immediately available, else raise `QueueEmpty`.

```python
task_done() → None
Indicate that a formerly enqueued task is complete.

Used by queue consumers. For each `get` used to fetch a task, a subsequent call to `task_done` tells the queue that the processing on the task is complete.

If a `join` is blocking, it resumes when all items have been processed; that is, when every `put` is matched by a `task_done`.

Raises `ValueError` if called more times than `put`.

```python
join(timeout: Optional[Union[float, timedelta]] = None) → Awaitable[None]
Block until all items in the queue are processed.

Returns an awaitable, which raises `tornado.util.TimeoutError` after a timeout.

**PriorityQueue**

class `tornado.queues.PriorityQueue`(maxsize: `int` = 0)
A `Queue` that retrieves entries in priority order, lowest first.

Entries are typically tuples like `(priority number, data)`.

```python
import asyncio
from tornado.queues import PriorityQueue

async def main():
    q = PriorityQueue()
    q.put((1, 'medium-priority item'))
    q.put((0, 'high-priority item'))
    q.put((10, 'low-priority item'))

    print(await q.get())
    print(await q.get())
    print(await q.get())

asyncio.run(main())
```

6.5. Coroutines and concurrency
(0, 'high-priority item')
(1, 'medium-priority item')
(10, 'low-priority item')

**LifoQueue**

```python
import asyncio
from tornado.queues import LifoQueue

async def main():
    q = LifoQueue()
    q.put(3)
    q.put(2)
    q.put(1)
    print(await q.get())
    print(await q.get())
    print(await q.get())

asyncio.run(main())
```

**Exceptions**

**QueueEmpty**

```python
exception tornado.queues.QueueEmpty

Raised by Queue.get_nowait when the queue has no items.
```

**QueueFull**

```python
exception tornado.queues.QueueFull

Raised by Queue.put_nowait when a queue is at its maximum size.
```
6.5.4 `tornado.process` — Utilities for multiple processes

Utilities for working with multiple processes, including both forking the server into multiple processes and managing subprocesses.

**exception** `tornado.process.CalledProcessError`

`tornado.process.cpu_count()` → `int`

Returns the number of processors on this machine.

`tornado.process.fork_processes(num_processes: Optional[int], max_restarts: Optional[int] = None) → int`

Starts multiple worker processes.

If `num_processes` is None or <= 0, we detect the number of cores available on this machine and fork that number of child processes. If `num_processes` is given and > 0, we fork that specific number of sub-processes.

Since we use processes and not threads, there is no shared memory between any server code.

Note that multiple processes are not compatible with the autoreload module (or the `autoreload=True` option to `tornado.web.Application` which defaults to True when `debug=True`). When using multiple processes, no IOLoops can be created or referenced until after the call to `fork_processes`.

In each child process, `fork_processes` returns its `task_id`, a number between 0 and `num_processes`. Processes that exit abnormally (due to a signal or non-zero exit status) are restarted with the same id (up to `max_restarts` times). In the parent process, `fork_processes` calls `sys.exit(0)` after all child processes have exited normally.

`max_restarts` defaults to 100.

Availability: Unix

`tornado.process.task_id()` → `Optional[int]`

Returns the current task id, if any.

Returns None if this process was not created by `fork_processes`.

**class** `tornado.process.Subprocess(*args: Any, **kwargs: Any)`

Wraps `subprocess.Popen` with IOStream support.

The constructor is the same as `subprocess.Popen` with the following additions:

- `stdin`, `stdout`, and `stderr` may have the value `tornado.process.Subprocess.STREAM`, which will make the corresponding attribute of the resulting Subprocess a `PipeIOStream`. If this option is used, the caller is responsible for closing the streams when done with them.

The `Subprocess.STREAM` option and the `set_exit_callback` and `wait_for_exit` methods do not work on Windows. There is therefore no reason to use this class instead of `subprocess.Popen` on that platform.

Changed in version 5.0: The `io_loop` argument (deprecated since version 4.1) has been removed.

`set_exit_callback(callback: Callable[[int], None]) → None`

Runs callback when this process exits.

The callback takes one argument, the return code of the process.

This method uses a SIGCHLD handler, which is a global setting and may conflict if you have other libraries trying to handle the same signal. If you are using more than one IOLoop it may be necessary to call `Subprocess.initialize` first to designate one IOLoop to run the signal handlers.

In many cases a close callback on the stdout or stderr streams can be used as an alternative to an exit callback if the signal handler is causing a problem.
Availability: Unix

**wait_for_exit**(*raise_error: bool = True*) → *Future*[int]

Returns a *Future* which resolves when the process exits.

Usage:
```
ret = yield proc.wait_for_exit()
```

This is a coroutine-friendly alternative to *set_exit_callback* (and a replacement for the blocking *subprocess.Popen.wait*).

By default, raises *subprocess.CalledProcessError* if the process has a non-zero exit status. Use *wait_for_exit(raise_error=False)* to suppress this behavior and return the exit status without raising.

New in version 4.2.

Availability: Unix

classmethod *initialize()* → *None*

Initializes the SIGCHLD handler.

The signal handler is run on an *IOLoop* to avoid locking issues. Note that the *IOLoop* used for signal handling need not be the same one used by individual Subprocess objects (as long as the IOLoops are each running in separate threads).

Changed in version 5.0: The *io_loop* argument (deprecated since version 4.1) has been removed.

Availability: Unix

classmethod *uninitialize()* → *None*

Removes the SIGCHLD handler.

### 6.6 Integration with other services

#### 6.6.1 tornado.auth — Third-party login with OpenID and OAuth

This module contains implementations of various third-party authentication schemes.

All the classes in this file are class mixins designed to be used with the *tornado.web.RequestHandler* class. They are used in two ways:

- On a login handler, use methods such as *authenticate_redirect()*, *authorize_redirect()*, and *get_authenticated_user()* to establish the user’s identity and store authentication tokens to your database and/or cookies.

- In non-login handlers, use methods such as *facebook_request()* or *twitter_request()* to use the authentication tokens to make requests to the respective services.

They all take slightly different arguments due to the fact all these services implement authentication and authorization slightly differently. See the individual service classes below for complete documentation.

Example usage for Google OAuth:
```
class GoogleOAuth2LoginHandler(tornado.web.RequestHandler, tornado.auth.GoogleOAuth2Mixin):
    async def get(self):
        (continues on next page)"
```python
if self.get_argument('code', False):
    user = await self.get_authenticated_user(
        redirect_uri='http://your.site.com/auth/google',
        code=self.get_argument('code'))
    # Save the user with e.g. set_signed_cookie
else:
    self.authorize_redirect(
        redirect_uri='http://your.site.com/auth/google',
        client_id=self.settings['google_oauth']['key'],
        scope=['profile', 'email'],
        response_type='code',
        extra_params={'approval_prompt': 'auto'})
```

**Common protocols**

These classes implement the OpenID and OAuth standards. They will generally need to be subclassed to use them with any particular site. The degree of customization required will vary, but in most cases overriding the class attributes (which are named beginning with underscores for historical reasons) should be sufficient.

```python
class tornado.auth.OpenIdMixin
    Abstract implementation of OpenID and Attribute Exchange.
    
    Class attributes:
    • _OPENID_ENDPOINT: the identity provider’s URI.

authenticate_redirect(callback_uri: Optional[str] = None, ax_attrs: List[str] = ['name', 'email',
    'language', 'username']) → None

Redirects to the authentication URL for this service.

After authentication, the service will redirect back to the given callback URI with additional parameters including openid.mode.

We request the given attributes for the authenticated user by default (name, email, language, and username). If you don’t need all those attributes for your app, you can request fewer with the ax_attrs keyword argument.

Changed in version 6.0: The callback argument was removed and this method no longer returns an awaitable object. It is now an ordinary synchronous function.

coroutine get_authenticated_user(http_client: Optional[AsyncHTTPClient] = None) → Dict[str,
    Any]

Fetches the authenticated user data upon redirect.

This method should be called by the handler that receives the redirect from the authenticate_redirect() method (which is often the same as the one that calls it; in that case you would call get_authenticated_user if the openid.mode parameter is present and authenticate_redirect if it is not).

The result of this method will generally be used to set a cookie.

Changed in version 6.0: The callback argument was removed. Use the returned awaitable object instead.

get_auth_http_client() → AsyncHTTPClient

Returns the AsyncHTTPClient instance to be used for auth requests.

May be overridden by subclasses to use an HTTP client other than the default.
```
class tornado.auth.OAuthMixin

Abstract implementation of OAuth 1.0 and 1.0a.

See TwitterMixin below for an example implementation.

Class attributes:

• _OAUTH_AUTHORIZE_URL: The service’s OAuth authorization url.
• _OAUTH_ACCESS_TOKEN_URL: The service’s OAuth access token url.
• _OAUTH_VERSION: May be either “1.0” or “1.0a”.
• _OAUTH_NO_CALLBACKS: Set this to True if the service requires advance registration of callbacks.

Subclasses must also override the _oauth_get_user_future and _oauth_consumer_token methods.

Redirects the user to obtain OAuth authorization for this service.

The callback_uri may be omitted if you have previously registered a callback URI with the third-party service. For some services, you must use a previously-registered callback URI and cannot specify a callback via this method.

This method sets a cookie called _oauth_request_token which is subsequently used (and cleared) in get_authenticated_user for security purposes.

This method is asynchronous and must be called with await or yield (This is different from other auth*_redirect methods defined in this module). It calls RequestHandler.finish for you so you should not write any other response after it returns.

Changed in version 3.1: Now returns a Future and takes an optional callback, for compatibility with gen.coroutine.

Changed in version 6.0: The callback argument was removed. Use the returned awaitable object instead.

async get_authenticated_user(http_client: Optional[AsyncHTTPClient] = None) → Dict[str, Any]

Gets the OAuth authorized user and access token.

This method should be called from the handler for your OAuth callback URL to complete the registration process. We run the callback with the authenticated user dictionary. This dictionary will contain an access_key which can be used to make authorized requests to this service on behalf of the user. The dictionary will also contain other fields such as name, depending on the service used.

Changed in version 6.0: The callback argument was removed. Use the returned awaitable object instead.

_oauth_consumer_token() → Dict[str, Any]

Subclasses must override this to return their OAuth consumer keys.

The return value should be a dict with keys key and secret.

async _oauth_get_user_future(access_token: Dict[str, Any]) → Dict[str, Any]

Subclasses must override this to get basic information about the user.

Should be a coroutine whose result is a dictionary containing information about the user, which may have been retrieved by using access_token to make a request to the service.

The access token will be added to the returned dictionary to make the result of get_authenticated_user.

Changed in version 5.1: Subclasses may also define this method with async def.

Changed in version 6.0: A synchronous fallback to _oauth_get_user was removed.
get_auth_http_client() → AsyncHTTPClient

Returns the AsyncHTTPClient instance to be used for auth requests.

May be overridden by subclasses to use an HTTP client other than the default.

class tornado.auth.OAuth2Mixin

Abstract implementation of OAuth 2.0.

See FacebookGraphMixin or GoogleOAuth2Mixin below for example implementations.

Class attributes:

• _OAUTH_AUTHORIZE_URL: The service’s authorization url.
• _OAUTH_ACCESS_TOKEN_URL: The service’s access token url.

Redirects the user to obtain OAuth authorization for this service.

Some providers require that you register a redirect URL with your application instead of passing one via this method. You should call this method to log the user in, and then call get_authenticated_user in the handler for your redirect URL to complete the authorization process.

Changed in version 6.0: The callback argument and returned awaitable were removed; this is now an ordinary synchronous function.

coroutine oauth2_request(url: str, access_token: Optional[str] = None, post_args: Optional[Dict[str, Any]] = None, **args: Any) → Any

Fetches the given URL auth an OAuth2 access token.

If the request is a POST, post_args should be provided. Query string arguments should be given as keyword arguments.

Example usage:

class MainHandler(tornado.web.RequestHandler, tornado.auth.FacebookGraphMixin):
    @tornado.web.authenticated
    async def get(self):
        new_entry = await self.oauth2_request(
            "https://graph.facebook.com/me/feed",
            post_args={"message": "I am posting from my Tornado application!"},
            access_token=self.current_user["access_token"])

        if not new_entry:
            # Call failed; perhaps missing permission?
            self.authorize_redirect()
            return

        self.finish("Posted a message!")

New in version 4.3.

get_auth_http_client() → AsyncHTTPClient

Returns the AsyncHTTPClient instance to be used for auth requests.

May be overridden by subclasses to use an HTTP client other than the default.
New in version 4.3.

**Google**

```python
class tornado.auth.GoogleOAuth2Mixin
```

Google authentication using OAuth2.

In order to use, register your application with Google and copy the relevant parameters to your application settings.

- Go to the Google Dev Console at http://console.developers.google.com
- Select a project, or create a new one.
- In the sidebar on the left, select Credentials.
- Click CREATE CREDENTIALS and click OAuth client ID.
- Under Application type, select Web application.
- Name OAuth 2.0 client and click Create.

- Copy the “Client secret” and “Client ID” to the application settings as `{"google_oauth": {"key": CLIENT_ID, "secret": CLIENT_SECRET}}

New in version 3.2.

```python
def get_google_oauth_settings() -> Dict[str, str]
```

Return the Google OAuth 2.0 credentials that you created with [Google Cloud Platform](https://console.cloud.google.com/apis/credentials). The dict format is:

```python
{
    "key": "your_client_id", "secret": "your_client_secret"
}
```

If your credentials are stored differently (e.g. in a db) you can override this method for custom provision.

```python
```

Handles the login for the Google user, returning an access token.

The result is a dictionary containing an access_token field ([among others](https://developers.google.com/identity/protocols/OAuth2WebServer#handlingtheresponse)). Unlike other `get_authenticated_user` methods in this package, this method does not return any additional information about the user. The returned access token can be used with `OAuth2Mixin.oauth2_request` to request additional information (perhaps from [https://www.googleapis.com/oauth2/v2/userinfo](https://www.googleapis.com/oauth2/v2/userinfo))

Example usage:

```python
class GoogleOAuth2LoginHandler(tornado.web.RequestHandler,
                               tornado.auth.GoogleOAuth2Mixin):
    async def get(self):
        if self.get_argument('code', False):
            access = await self.get_authenticated_user(
                redirect_uri='http://your.site.com/auth/google',
                code=self.get_argument('code'))
            user = await self.oauth2_request(
                "https://www.googleapis.com/oauth2/v1/userinfo",
                access_token=access["access_token"])
```

(continues on next page)
# Save the user and access token with
# e.g. set_signed_cookie.

else:
    self.authorize_redirect(
        redirect_uri='http://your.site.com/auth/google',
        client_id=self.get_google_oauth_settings()['key'],
        scope=['profile', 'email'],
        response_type='code',
        extra_params={'approval_prompt': 'auto'})

Changed in version 6.0: The callback argument was removed. Use the returned awaitable object instead.

## Facebook

```python

class tornado.auth.FacebookGraphMixin

Facebook authentication using the new Graph API and OAuth2.

Handles the login for the Facebook user, returning a user object.

Example usage:

class FacebookGraphLoginHandler(tornado.web.RequestHandler, tornado.auth.FacebookGraphMixin):
    async def get(self):
        if self.get_argument("code", False):
            user = await self.get_authenticated_user(
                redirect_uri="/auth/facebookgraph/",
                client_id=self.settings["facebook_api_key"],
                client_secret=self.settings["facebook_secret"],
                code=self.get_argument("code"))
            # Save the user with e.g. set_signed_cookie
        else:
            self.authorize_redirect(
                redirect_uri="/auth/facebookgraph/",
                client_id=self.settings["facebook_api_key"],
                extra_params={"scope": "read_stream,offline_access"})
```

This method returns a dictionary which may contain the following fields:

- **access_token**, a string which may be passed to `facebook_request`
- **session_expires**, an integer encoded as a string representing the time until the access token expires in seconds. This field should be used like `int(user['session_expires'])`; in a future version of Tornado it will change from a string to an integer.
- **id, name, first_name, last_name, locale, picture, link**, plus any fields named in the `extra_fields` argument. These fields are copied from the Facebook graph API user object

Changed in version 4.5: The `session_expires` field was updated to support changes made to the Facebook API in March 2017.

Changed in version 6.0: The callback argument was removed. Use the returned awaitable object instead.

### 6.6. Integration with other services
coroutine **facebook_request** *(path: str, access_token: Optional[str] = None, post_args: Optional[Dict[str, Any]] = None, **args: Any)* → Any

Fetches the given relative API path, e.g., `/btaylor/picture`

If the request is a POST, *post_args* should be provided. Query string arguments should be given as keyword arguments.

An introduction to the Facebook Graph API can be found at [http://developers.facebook.com/docs/api](http://developers.facebook.com/docs/api)

Many methods require an OAuth access token which you can obtain through `authorize_redirect` and `get_authenticated_user`. The user returned through that process includes an `access_token` attribute that can be used to make authenticated requests via this method.

Example usage:

```python
class MainHandler(tornado.web.RequestHandler, tornado.auth.FacebookGraphMixin):
    @tornado.web.authenticated
    async def get(self):
        new_entry = await self.facebook_request(
            '/me/feed',
            post_args={'message': 'I am posting from my Tornado application!'},
            access_token=self.current_user['access_token'])

        if not new_entry:
            # Call failed; perhaps missing permission?
            self.authorize_redirect()
            return

        self.finish('Posted a message!')
```

The given path is relative to `self._FACEBOOK_BASE_URL`, by default “https://graph.facebook.com”.

This method is a wrapper around `OAuth2Mixin.oauth2_request`; the only difference is that this method takes a relative path, while `oauth2_request` takes a complete url.

Changed in version 3.1: Added the ability to override `self._FACEBOOK_BASE_URL`.

Changed in version 6.0: The `callback` argument was removed. Use the returned awaitable object instead.

### Twitter

class **tornado.auth.TwitterMixin**

Twitter OAuth authentication.

To authenticate with Twitter, register your application with Twitter at [http://twitter.com/apps](http://twitter.com/apps). Then copy your Consumer Key and Consumer Secret to the application `settings.twitter_consumer_key` and `twitter_consumer_secret`. Use this mixin on the handler for the URL you registered as your application’s callback URL.

When your application is set up, you can use this mixin like this to authenticate the user with Twitter and get access to their stream:

```python
class TwitterLoginHandler(tornado.web.RequestHandler, tornado.auth.TwitterMixin):
    async def get(self):
        if self.get_argument('oauth_token', None):
            user = await self.get_authenticated_user()
```

(continues on next page)
The user object returned by `get_authenticated_user` includes the attributes `username`, `name`, `access_token`, and all of the custom Twitter user attributes described at https://dev.twitter.com/docs/api/1.1/get/users/show

```python
coroutine authenticate_redirect(callback_uri: Optional[str] = None) → None
```

Just like `authorize_redirect`, but auto-redirects if authorized.

This is generally the right interface to use if you are using Twitter for single-sign on.

Changed in version 3.1: Now returns a `Future` and takes an optional callback, for compatibility with `gen.coroutine`.

Changed in version 6.0: The callback argument was removed. Use the returned awaitable object instead.

```python
coroutine twitter_request(path: str, access_token: Dict[str, Any], post_args: Optional[Dict[str, Any]] = None, **args: Any) → Any
```

Fetches the given API path, e.g., `statuses/user_timeline/btaylor`.

The path should not include the format or API version number. (we automatically use JSON format and API version 1).

If the request is a POST, `post_args` should be provided. Query string arguments should be given as keyword arguments.

All the Twitter methods are documented at http://dev.twitter.com/

Many methods require an OAuth access token which you can obtain through `authorize_redirect` and `get_authenticated_user`. The user returned through that process includes an ‘access_token’ attribute that can be used to make authenticated requests via this method. Example usage:

```python
class MainHandler(tornado.web.RequestHandler, tornado.auth.TwitterMixin):
    @tornado.web.authenticated
    async def get(self):
        new_entry = await self.twitter_request("/statuses/update",
                                          post_args={"status": "Testing Tornado Web Server"},
                                          access_token=self.current_user["access_token"])
        if not new_entry:
            # Call failed; perhaps missing permission?
            await self.authorize_redirect()
            return
        self.finish("Posted a message!")
```

Changed in version 6.0: The callback argument was removed. Use the returned awaitable object instead.
## 6.6.2 tornado.wsgi — Interoperability with other Python frameworks and servers

WSGI support for the Tornado web framework.

WSGI is the Python standard for web servers, and allows for interoperability between Tornado and other Python web frameworks and servers.

This module provides WSGI support via the `tornado.wsgi.WSGIContainer` class, which makes it possible to run applications using other WSGI frameworks on the Tornado HTTP server. The reverse is not supported; the Tornado `Application` and `RequestHandler` classes are designed for use with the Tornado `HTTPServer` and cannot be used in a generic WSGI container.

```python
class tornado.wsgi.WSGIContainer(wsgi_application: WSGIAppType, executor: Optional[Executor] = None):
    """Makes a WSGI-compatible application runnable on Tornado's HTTP server."
```

**Warning:** WSGI is a synchronous interface, while Tornado’s concurrency model is based on single-threaded asynchronous execution. Many of Tornado’s distinguishing features are not available in WSGI mode, including efficient long-polling and websockets. The primary purpose of `tornado.wsgi.WSGIContainer` is to support both WSGI applications and native Tornado `RequestHandler` classes in a single process. WSGI-only applications are likely to be better off with a dedicated WSGI server such as `gunicorn` or `uwsgi`.

Wrap a WSGI application in a `tornado.wsgi.WSGIContainer` to make it implement the Tornado `HTTPServer` request_callback interface. The `tornado.wsgi.WSGIContainer` object can then be passed to classes from the `tornado.routing` module, `tornado.web.FallbackHandler`, or to `HTTPServer` directly.

This class is intended to let other frameworks (Django, Flask, etc) run on the Tornado HTTP server and I/O loop.

Realistic usage will be more complicated, but the simplest possible example uses a hand-written WSGI application with `HTTPServer`:

```python
def simple_app(environ, start_response):
    status = "200 OK"
    response_headers = ["Content-type", "text/plain"]
    start_response(status, response_headers)
    return [b"Hello world!\n"

async def main():
    container = tornado.wsgi.WSGIContainer(simple_app)
    http_server = tornado.httpserver.HTTPServer(container)
    http_server.listen(8888)
    await asyncio.Event().wait()

asyncio.run(main())
```

The recommended pattern is to use the `tornado.routing` module to set up routing rules between your WSGI application and, typically, a `tornado.web.Application`. Alternatively, `tornado.web.Application` can be used as the top-level router and `tornado.web.FallbackHandler` can embed a `tornado.wsgi.WSGIContainer` within it.

If the `executor` argument is provided, the WSGI application will be executed on that executor. This must be an instance of `concurrent.futures.Executor`, typically a `ThreadPoolExecutor` (`ProcessPoolExecutor` is not supported). If no `executor` is given, the application will run on the event loop thread in Tornado 6.3; this will change to use an internal thread pool by default in Tornado 7.0.
Warning: By default, the WSGI application is executed on the event loop’s thread. This limits the server to one request at a time (per process), making it less scalable than most other WSGI servers. It is therefore highly recommended that you pass a ThreadPoolExecutor when constructing the WSGIContainer, after verifying that your application is thread-safe. The default will change to use a ThreadPoolExecutor in Tornado 7.0.

New in version 6.3: The executor parameter.

Deprecated since version 6.3: The default behavior of running the WSGI application on the event loop thread is deprecated and will change in Tornado 7.0 to use a thread pool by default.

environ(request: HTTPServerRequest) → Dict[str, Any]

Converts a tornado.httputil.HTTPServerRequest to a WSGI environment.

Changed in version 6.3: No longer a static method.

6.6.3 tornado.platform.caresresolver — Asynchronous DNS Resolver using C-Ares

This module contains a DNS resolver using the c-ares library (and its wrapper pycares).

class tornado.platform.caresresolver.CaresResolver

Name resolver based on the c-ares library.

This is a non-blocking and non-threaded resolver. It may not produce the same results as the system resolver, but can be used for non-blocking resolution when threads cannot be used.

c-ares fails to resolve some names when family is AF_UNSPEC, so it is only recommended for use in AF_INET (i.e. IPv4). This is the default for tornado.simple_httpclient, but other libraries may default to AF_UNSPEC.

Deprecated since version 6.2: This class is deprecated and will be removed in Tornado 7.0. Use the default thread-based resolver instead.

6.6.4 tornado.platform.twisted — Bridges between Twisted and Tornado

Deprecated since version 6.0: This module is no longer recommended for new code. Instead of using direct integration between Tornado and Twisted, new applications should rely on the integration with asyncio provided by both packages.

Importing this module has the side effect of registering Twisted’s Deferred class with Tornado’s @gen.coroutine so that Deferred objects can be used with yield in coroutines using this decorator (importing this module has no effect on native coroutines using async def).

tornado.platform.twisted.install()

Install AsyncioSelectorReactor as the default Twisted reactor.

Deprecated since version 5.1: This function is provided for backwards compatibility; code that does not require compatibility with older versions of Tornado should use twisted.internet.asyncioreactor.install() directly.

Changed in version 6.0.3: In Tornado 5.x and before, this function installed a reactor based on the Tornado IOLoop. When that reactor implementation was removed in Tornado 6.0.0, this function was removed as well. It was restored in Tornado 6.0.3 using the asyncio reactor instead.
Twisted DNS resolver

class tornado.platform.twisted.TwistedResolver

Twisted-based asynchronous resolver.

This is a non-blocking and non-threaded resolver. It is recommended only when threads cannot be used, since it has limitations compared to the standard getaddrinfo-based Resolver and DefaultExecutorResolver. Specifically, it returns at most one result, and arguments other than host and family are ignored. It may fail to resolve when family is not socket.AF_UNSPEC.

Requires Twisted 12.1 or newer.

Changed in version 5.0: The io_loop argument (deprecated since version 4.1) has been removed.

Deprecated since version 6.2: This class is deprecated and will be removed in Tornado 7.0. Use the default thread-based resolver instead.

6.6.5 tornado.platform.asyncio — Bridge between asyncio and Tornado

Bridges between the asyncio module and Tornado IOLoop.

New in version 3.2.

This module integrates Tornado with the asyncio module introduced in Python 3.4. This makes it possible to combine the two libraries on the same event loop.

Deprecated since version 5.0: While the code in this module is still used, it is now enabled automatically when asyncio is available, so applications should no longer need to refer to this module directly.

Note: Tornado is designed to use a selector-based event loop. On Windows, where a proactor-based event loop has been the default since Python 3.8, a selector event loop is emulated by running select on a separate thread. Configuring asyncio to use a selector event loop may improve performance of Tornado (but may reduce performance of other asyncio-based libraries in the same process).

class tornado.platform.asyncio.AsyncIOMainLoop(*args: Any, **kwargs: Any)

AsyncIOMainLoop creates an IOLoop that corresponds to the current asyncio event loop (i.e. the one returned by asyncio.get_event_loop()).

Deprecated since version 5.0: Now used automatically when appropriate; it is no longer necessary to refer to this class directly.

Changed in version 5.0: Closing an AsyncIOMainLoop now closes the underlying asyncio loop.

class tornado.platform.asyncio.AsyncIOLoop(*args: Any, **kwargs: Any)

AsyncIOLoop is an IOLoop that runs on an asyncio event loop. This class follows the usual Tornado semantics for creating new IOLoops; these loops are not necessarily related to the asyncio default event loop.

Each AsyncIOLoop creates a new asyncio.EventLoop; this object can be accessed with the asyncio_loop attribute.

Changed in version 6.2: Support explicit asyncio_loop argument for specifying the asyncio loop to attach to, rather than always creating a new one with the default policy.

Changed in version 5.0: When an AsyncIOLoop becomes the current IOLoop, it also sets the current asyncio event loop.

Deprecated since version 5.0: Now used automatically when appropriate; it is no longer necessary to refer to this class directly.
tornado.platform.asyncio.to_tornado_future(asyncio_future: Future) → Future
Convert an asyncio.Future to a tornado.concurrent.Future.
New in version 4.1.
Deprecated since version 5.0: Tornado Futures have been merged with asyncio.Future, so this method is now a no-op.

Tornado Documentation, Release 6.4.dev1

6.6. Integration with other services 145

tornado.platform.asyncio.to_asyncio_future(tornado_future: Future) → Future
Convert a Tornado yieldable object to an asyncio.Future.
New in version 4.1.
Deprecated since version 5.0: Tornado Futures have been merged with asyncio.Future, so this method is now equivalent to tornado.gen.convert_yielded.

class tornado.platform.asyncio.AnyThreadEventLoopPolicy
Event loop policy that allows loop creation on any thread.
The default asyncio event loop policy only automatically creates event loops in the main threads. Other threads must create event loops explicitly or asyncio.get_event_loop (and therefore IOLoop.current) will fail. Installing this policy allows event loops to be created automatically on any thread, matching the behavior of Tornado versions prior to 5.0 (or 5.0 on Python 2).
Usage:

asyncio.set_event_loop_policy(AnyThreadEventLoopPolicy())
New in version 5.0.
Deprecated since version 6.2: AnyThreadEventLoopPolicy affects the implicit creation of an event loop, which is deprecated in Python 3.10 and will be removed in a future version of Python. At that time AnyThreadEventLoopPolicy will no longer be useful. If you are relying on it, use asyncio.new_event_loop or asyncio.run explicitly in any non-main threads that need event loops.

class tornado.platform.asyncio.SelectorThread(real_loop: AbstractEventLoop)
Define add_reader methods to be called in a background select thread.
Instances of this class start a second thread to run a selector. This thread is completely hidden from the user; all callbacks are run on the wrapped event loop’s thread.
Typically used via AddThreadSelectorEventLoop, but can be attached to a running asyncio loop.

class tornado.platform.asyncio.AddThreadSelectorEventLoop(real_loop: AbstractEventLoop)
Wrap an event loop to add implementations of the add_reader method family.
Instances of this class start a second thread to run a selector. This thread is completely hidden from the user; all callbacks are run on the wrapped event loop’s thread.
This class is used automatically by Tornado; applications should not need to refer to it directly.
It is safe to wrap any event loop with this class, although it only makes sense for event loops that do not implement the add_reader family of methods themselves (i.e. WindowsProactorEventLoop)
Closing the AddThreadSelectorEventLoop also closes the wrapped event loop.
6.7 Utilities

6.7.1 tornado.autoreload — Automatically detect code changes in development

Automatically restart the server when a source file is modified.

Most applications should not access this module directly. Instead, pass the keyword argument autoreload=True to the tornado.web.Application constructor (or debug=True, which enables this setting and several others). This will enable autoreload mode as well as checking for changes to templates and static resources. Note that restarting is a destructive operation and any requests in progress will be aborted when the process restarts. (If you want to disable autoreload while using other debug-mode features, pass both debug=True and autoreload=False). This module can also be used as a command-line wrapper around scripts such as unit test runners. See the main method for details.

The command-line wrapper and Application debug modes can be used together. This combination is encouraged as the wrapper catches syntax errors and other import-time failures, while debug mode catches changes once the server has started.

This module will not work correctly when HTTPServer’s multi-process mode is used.

Reloading loses any Python interpreter command-line arguments (e.g. -u) because it re-executes Python using sys.executable and sys.argv. Additionally, modifying these variables will cause reloading to behave incorrectly.

\[
\text{tornado.autoreload.start}(\text{check\_time: int} = 500) \rightarrow \text{None}
\]

Begins watching source files for changes.

Changed in version 5.0: The io_loop argument (deprecated since version 4.1) has been removed.

\[
\text{tornado.autoreload.wait()} \rightarrow \text{None}
\]

Wait for a watched file to change, then restart the process.

Intended to be used at the end of scripts like unit test runners, to run the tests again after any source file changes (but see also the command-line interface in main).

\[
\text{tornado.autoreload.watch}(\text{filename: str}) \rightarrow \text{None}
\]

Add a file to the watch list.

All imported modules are watched by default.

\[
\text{tornado.autoreload.add\_reload\_hook}(\text{fn: Callable[[], None]}) \rightarrow \text{None}
\]

Add a function to be called before reloading the process.

Note that for open file and socket handles it is generally preferable to set the FD_CLOEXEC flag (using fcntl or os.set_inheritable) instead of using a reload hook to close them.

\[
\text{tornado.autoreload.main()} \rightarrow \text{None}
\]

Command-line wrapper to re-run a script whenever its source changes.

Scripts may be specified by filename or module name:

```
python -m tornado.autoreload -m tornado.test.runtests
python -m tornado.autoreload tornado/test/runtests.py
```

Running a script with this wrapper is similar to calling tornado.autoreload.wait at the end of the script, but this wrapper can catch import-time problems like syntax errors that would otherwise prevent the script from reaching its call to wait.
6.7.2 tornado.concurrent — Work with Future objects

Utilities for working with Future objects.

Tornado previously provided its own Future class, but now uses asyncio.Future. This module contains utility functions for working with asyncio.Future in a way that is backwards-compatible with Tornado’s old Future implementation.

While this module is an important part of Tornado’s internal implementation, applications rarely need to interact with it directly.

class tornado.concurrent.Future

tornado.concurrent.Future is an alias for asyncio.Future.

In Tornado, the main way in which applications interact with Future objects is by awaiting or yielding them in coroutines, instead of calling methods on the Future objects themselves. For more information on the available methods, see the asyncio.Future docs.

Changed in version 5.0: Tornado’s implementation of Future has been replaced by the version from asyncio when available.

- Future objects can only be created while there is a current IOLoop
- The timing of callbacks scheduled with Future.add_done_callback has changed.
- Cancellation is now partially supported (only on Python 3)
- The exc_info and set_exc_info methods are no longer available on Python 3.

tornado.concurrent.run_on_executor(*args: Any, **kwargs: Any) → Callable

Decorator to run a synchronous method asynchronously on an executor. Returns a future.

The executor to be used is determined by the executor attributes of self. To use a different attribute name, pass a keyword argument to the decorator:

```python
@run_on_executor(executor='__thread_pool')
def foo(self):
    pass
```

This decorator should not be confused with the similarly-named IOLoop.run_in_executor. In general, using run_in_executor when calling a blocking method is recommended instead of using this decorator when defining a method. If compatibility with older versions of Tornado is required, consider defining an executor and using executor.submit() at the call site.

Changed in version 4.2: Added keyword arguments to use alternative attributes.

Changed in version 5.0: Always uses the current IOLoop instead of self.io_loop.

Changed in version 5.1: Returns a Future compatible with await instead of a concurrent.futures.Future.

Deprecated since version 5.1: The callback argument is deprecated and will be removed in 6.0. The decorator itself is discouraged in new code but will not be removed in 6.0.

Changed in version 6.0: The callback argument was removed.

tornado.concurrent.chain_future(a: Future[_T], b: Future[_T]) → None

Chain two futures together so that when one completes, so does the other.

The result (success or failure) of a will be copied to b, unless b has already been completed or cancelled by the time a finishes.
Changed in version 5.0: Now accepts both Tornado/asyncio `Future` objects and `concurrent.futures.Future`.

`tornado.concurrent.future_set_result_unless_cancelled(future: Union[futures.Future[_T], Future[_T]], value: _T) → None`

Set the given value as the `Future`'s result, if not cancelled.

Avoids `asyncio.InvalidStateError` when calling `set_result()` on a cancelled `asyncio.Future`.

New in version 5.0.

`tornado.concurrent.future_set_exception_unless_cancelled(future: Union[futures.Future[_T], Future[_T]], exc: BaseException) → None`

Set the given `exc` as the `Future`'s exception.

If the Future is already canceled, logs the exception instead. If this logging is not desired, the caller should explicitly check the state of the Future and call `Future.set_exception` instead of this wrapper.

Avoids `asyncio.InvalidStateError` when calling `set_exception()` on a cancelled `asyncio.Future`.

New in version 6.0.

`tornado.concurrent.future_set_exc_info(future: Union[futures.Future[_T], Future[_T]], exc_info: Tuple[Optional[type], Optional[BaseException], Optional[TracebackType]]) → None`

Set the given `exc_info` as the `Future`'s exception.

Understands both `asyncio.Future` and the extensions in older versions of Tornado to enable better tracebacks on Python 2.

New in version 5.0.

Changed in version 6.0: If the future is already cancelled, this function is a no-op. (previously `asyncio.InvalidStateError` would be raised)

`tornado.concurrent.future_add_done_callback(future: futures.Future[_T], callback: Callable[[futures.Future[_T]], None]) → None`

`tornado.concurrent.future_add_done_callback(future: Future[_T], callback: Callable[[Future[_T]], None]) → None`

Arrange to call `callback` when `future` is complete.

`callback` is invoked with one argument, the `future`.

If `future` is already done, `callback` is invoked immediately. This may differ from the behavior of `Future.add_done_callback`, which makes no such guarantee.

New in version 5.0.

### 6.7.3 `tornado.log` — Logging support

Logging support for Tornado.

Tornado uses three logger streams:

- `tornado.access`: Per-request logging for Tornado’s HTTP servers (and potentially other servers in the future)
- `tornado.application`: Logging of errors from application code (i.e. uncaught exceptions from callbacks)
- `tornado.general`: General-purpose logging, including any errors or warnings from Tornado itself.
These streams may be configured independently using the standard library’s `logging` module. For example, you may wish to send `tornado.access` logs to a separate file for analysis.

```python
class tornado.log.LogFormatter(fmt: str = '%(color)s%(levelname)1.1s%(asctime)s
%(module)s:%(lineno)d%(end_color)s%(message)s', datefmt: str = '%y%m%d %H:%M:%S', style: str = '%', color: bool = True, colors: Dict[int, int] = {10: 4, 20: 2, 30: 3, 40: 1, 50: 5})
```

Log formatter used in Tornado.

Key features of this formatter are:

- Color support when logging to a terminal that supports it.
- Timestamps on every log line.
- Robust against str/bytes encoding problems.

This formatter is enabled automatically by `tornado.options.parse_command_line` or `tornado.options.parse_config_file` (unless `--logging=none` is used).

Color support on Windows versions that do not support ANSI color codes is enabled by use of the `colorama` library. Applications that wish to use this must first initialize colorama with a call to `colorama.init`. See the colorama documentation for details.

Changed in version 4.5: Added support for `colorama`. Changed the constructor signature to be compatible with `logging.config.dictConfig`.

**Parameters**

- **color** (*bool*) – Enables color support.
- **fmt** (*str*) – Log message format. It will be applied to the attributes dict of log records. The text between `%(color)s` and `%end_color)s` will be colored depending on the level if color support is on.
- **colors** (*dict*) – color mappings from logging level to terminal color code
- **datefmt** (*str*) – Datetime format. Used for formatting `(asctime)` placeholder in `prefix_fmt`.

changed in version 3.2: Added `fmt` and `datefmt` arguments.

```
tornado.log.enable_pretty_logging(options: Optional[Any] = None, logger: Optional[Logger] = None) -> None
```

Turns on formatted logging output as configured.

This is called automatically by `tornado.options.parse_command_line` and `tornado.options.parse_config_file`.

```
tornado.log.define_logging_options(options: Optional[Any] = None) -> None
```

Add logging-related flags to `options`.

These options are present automatically on the default options instance; this method is only necessary if you have created your own `OptionParser`.

New in version 4.2: This function existed in prior versions but was broken and undocumented until 4.2.
6.7.4 tornado.options — Command-line parsing

A command line parsing module that lets modules define their own options.

This module is inspired by Google’s gflags. The primary difference with libraries such as argparse is that a global registry is used so that options may be defined in any module (it also enables tornado.log by default). The rest of Tornado does not depend on this module, so feel free to use argparse or other configuration libraries if you prefer them.

Options must be defined with tornado.options.define before use, generally at the top level of a module. The options are then accessible as attributes of tornado.options.options:

```python
# myapp/db.py
from tornado.options import define, options

define("mysql_host", default="127.0.0.1:3306", help="Main user DB")
define("memcache_hosts", default="127.0.0.1:11011", multiple=True,
       help="Main user memcache servers")

def connect():
    db = database.Connection(options.mysql_host)
    ...

# myapp/server.py
from tornado.options import define, options

define("port", default=8080, help="port to listen on")

def start_server():
    app = make_app()
    app.listen(options.port)
```

The main() method of your application does not need to be aware of all of the options used throughout your program; they are all automatically loaded when the modules are loaded. However, all modules that define options must have been imported before the command line is parsed.

Your main() method can parse the command line or parse a config file with either parse_command_line or parse_config_file:

```python
import myapp.db, myapp.server
import tornado

if __name__ == '__main__':
    tornado.options.parse_command_line()
    # or
    tornado.options.parse_config_file("/etc/server.conf")
```

Note: When using multiple parse_* functions, pass final=False to all but the last one, or side effects may occur twice (in particular, this can result in log messages being doubled).

tornado.options.options is a singleton instance of OptionParser, and the top-level functions in this module (define, parse_command_line, etc) simply call methods on it. You may create additional OptionParser instances to define isolated sets of options, such as for subcommands.
Note: By default, several options are defined that will configure the standard logging module when `parse_command_line` or `parse_config_file` are called. If you want Tornado to leave the logging configuration alone so you can manage it yourself, either pass `--logging=none` on the command line or do the following to disable it in code:

```python
from tornado.options import options, parse_command_line
options.logging = None
parse_command_line()
```

Note: `parse_command_line` or `parse_config_file` function should called after logging configuration and user-defined command line flags using the `callback` option definition, or these configurations will not take effect.

Changed in version 4.3: Dashes and underscores are fully interchangeable in option names; options can be defined, set, and read with any mix of the two. Dashes are typical for command-line usage while config files require underscores.

**Global functions**

tornado.options.define(*name: str, default: Optional[Any] = None, type: Optional[type] = None, help: Optional[str] = None, metavar: Optional[str] = None, multiple: bool = False, group: Optional[str] = None, callback: Optional[Callable[[Any], None]] = None*) → None

Defines an option in the global namespace.

See `OptionParser.define`.

tornado.options.options

Global options object. All defined options are available as attributes on this object.

tornado.options.parse_command_line(*args: Optional[List[str]] = None, final: bool = True*) → List[str]

Parses global options from the command line.

See `OptionParser.parse_command_line`.

tornado.options.parse_config_file(*path: str, final: bool = True*) → None

Parses global options from a config file.

See `OptionParser.parse_config_file`.

tornado.options.print_help(*file=sys.stderr*)

Prints all the command line options to stderr (or another file).

See `OptionParser.print_help`.

tornado.options.add_parse_callback(*callback: Callable[[], None]*) → None

Adds a parse callback, to be invoked when option parsing is done.

See `OptionParser.add_parse_callback`.

exception tornado.options.Error

Exception raised by errors in the options module.
OptionParser class

class tornado.options.OptionParser

A collection of options, a dictionary with object-like access.

Normally accessed via static functions in the tornado.options module, which reference a global instance.

OptionParser.define(name: str, default: Optional[Any] = None, type: Optional[type] = None, help: Optional[str] = None, metavar: Optional[str] = None, multiple: bool = False, group: Optional[str] = None, callback: Optional[Callable[[Any], None]] = None) → None

Defines a new command line option.

type can be any of str, int, float, bool, datetime, or timedelta. If no type is given but a default is, type is the type of default. Otherwise, type defaults to str.

If multiple is True, the option value is a list of type instead of an instance of type.

help and metavar are used to construct the automatically generated command line help string. The help message is formatted like:

```
--name=METAVAR help string
```

group is used to group the defined options in logical groups. By default, command line options are grouped by the file in which they are defined.

Command line option names must be unique globally.

If a callback is given, it will be run with the new value whenever the option is changed. This can be used to combine command-line and file-based options:

```python
define("config", type=str, help="path to config file",
       callback=lambda path: parse_config_file(path, final=final(False)))
```

With this definition, options in the file specified by --config will override options set earlier on the command line, but can be overridden by later flags.

OptionParser.parse_command_line(args: Optional[List[str]] = None, final: bool = True) → List[str]

Parses all options given on the command line (defaults to sys.argv).

Options look like --option=value and are parsed according to their type. For boolean options, --option is equivalent to --option=true

If the option has multiple=True, comma-separated values are accepted. For multi-value integer options, the syntax x:y is also accepted and equivalent to range(x, y).

Note that args[0] is ignored since it is the program name in sys.argv.

We return a list of all arguments that are not parsed as options.

If final is False, parse callbacks will not be run. This is useful for applications that wish to combine configurations from multiple sources.

OptionParser.parse_config_file(path: str, final: bool = True) → None

Parses and loads the config file at the given path.

The config file contains Python code that will be executed (so it is not safe to use untrusted config files). Anything in the global namespace that matches a defined option will be used to set that option’s value.

Options may either be the specified type for the option or strings (in which case they will be parsed the same way as in parse_command_line)

Example (using the options defined in the top-level docs of this module):
port = 80
mysql_host = 'mydb.example.com:3306'
# Both lists and comma-separated strings are allowed for
# multiple=True.
memcache_hosts = ['cache1.example.com:11011',
'cache2.example.com:11011']
memcache_hosts = 'cache1.example.com:11011,cache2.example.com:11011'

If final is False, parse callbacks will not be run. This is useful for applications that wish to combine configurations from multiple sources.

**Note:** tornado.options is primarily a command-line library. Config file support is provided for applications that wish to use it, but applications that prefer config files may wish to look at other libraries instead.

Changed in version 4.1: Config files are now always interpreted as utf-8 instead of the system default encoding. Changed in version 4.4: The special variable `__file__` is available inside config files, specifying the absolute path to the config file itself.

Changed in version 5.1: Added the ability to set options via strings in config files.

OptionParser.print_help(file: Optional[TextIO] = None) → None
Prints all the command line options to stderr (or another file).

OptionParser.add_parse_callback(callback: Callable[[], None]) → None
Adds a parse callback, to be invoked when option parsing is done.

OptionParser.mockable() → _Mockable
Returns a wrapper around self that is compatible with mock.patch.

The mock.patch function (included in the standard library unittest.mock package since Python 3.3, or in the third-party mock package for older versions of Python) is incompatible with objects like options that override __getattr__ and __setattr__. This function returns an object that can be used with mock.patch.object to modify option values:

```python
with mock.patch.object(options.mockable(), 'name', value):
    assert options.name == value
```

OptionParser.items() → Iterable[Tuple[str, Any]]
An iterable of (name, value) pairs.

New in version 3.1.

OptionParser.as_dict() → Dict[str, Any]
The names and values of all options.

New in version 3.1.

OptionParser.groups() → Set[str]
The set of option-groups created by define.

New in version 3.1.

OptionParser.group_dict(group: str) → Dict[str, Any]
The names and values of options in a group.

Useful for copying options into Application settings:
from tornado.options import define, parse_command_line, options

define('template_path', group='application')
define('static_path', group='application')

parse_command_line()

application = Application(
    handlers, **options.group_dict('application'))

New in version 3.1.

6.7.5 tornado.testing — Unit testing support for asynchronous code

Support classes for automated testing.

- AsyncTestCase and AsyncHTTPTestCase: Subclasses of unittest.TestCase with additional support for testing asynchronous (IOLoop-based) code.
- ExpectLog: Make test logs less spammy.
- main(): A simple test runner (wrapper around unittest.main()) with support for the tornado.autoreload module to rerun the tests when code changes.

Asynchronous test cases

class tornado.testing.AsyncTestCase(methodName: str = 'runTest')
    
    TestCase subclass for testing IOLoop-based asynchronous code.

    The unittest framework is synchronous, so the test must be complete by the time the test method returns. This means that asynchronous code cannot be used in quite the same way as usual and must be adapted to fit. To write your tests with coroutines, decorate your test methods with tornado.testing.gen_test instead of tornado.gen.coroutine.

    This class also provides the (deprecated) stop() and wait() methods for a more manual style of testing. The test method itself must call self.wait(), and asynchronous callbacks should call self.stop() to signal completion.

    By default, a new IOLoop is constructed for each test and is available as self.io_loop. If the code being tested requires a reused global IOLoop, subclasses should override get_new_ioloop to return it, although this is deprecated as of Tornado 6.3.

    The IOLoop’s start and stop methods should not be called directly. Instead, use self.stop and self.wait. Arguments passed to self.stop are returned from self.wait. It is possible to have multiple wait/stop cycles in the same test.

Example:

# This test uses coroutine style.
class MyTestCasse(AsyncTestCase):
    @tornado.testing.gen_test
    def test_http_fetch(self):
        client = AsyncHTTPClient()
        response = yield client.fetch("http://www.tornadoweb.org")
        # Test contents of response

(continues on next page)
def test_http_fetch(self):
    client = AsyncHTTPClient()
    client.fetch("http://www.tornadoweb.org/", self.stop)
    response = self.wait()

    self.assertIn("FriendFeed", response.body)

# This test uses argument passing between self.stop and self.wait.
class MyTestCase2(AsyncTestCase):
    def test_http_fetch(self):
        client = AsyncHTTPClient()
        client.fetch("http://www.tornadoweb.org/", self.stop)
        response = self.wait()

        self.assertIn("FriendFeed", response.body)

get_new_ioloop() → IOLoop

Returns the IOLoop to use for this test.

By default, a new IOLoop is created for each test. Subclasses may override this method to return IOLoop.
current() if it is not appropriate to use a new IOLoop in each tests (for example, if there are global
singletons using the default IOLoop) or if a per-test event loop is being provided by another system (such
as pytest-asyncio).

Deprecated since version 6.3: This method will be removed in Tornado 7.0.

stop(_arg: Optional[Any] = None, **kwargs: Any) → None

Stops the IOLoop, causing one pending (or future) call to wait() to return.

Keyword arguments or a single positional argument passed to stop() are saved and will be returned by
wait().

Deprecated since version 5.1: stop and wait are deprecated; use @gen_test instead.

wait(condition: Optional[Callable[..., bool]] = None, timeout: Optional[float] = None) → Any

Runs the IOLoop until stop is called or timeout has passed.

In the event of a timeout, an exception will be thrown. The default timeout is 5 seconds; it may be overridden
with a timeout keyword argument or globally with the ASYNC_TEST_TIMEOUT environment variable.

If condition is not None, the IOLoop will be restarted after stop() until condition() returns True.

Changed in version 3.1: Added the ASYNC_TEST_TIMEOUT environment variable.

Deprecated since version 5.1: stop and wait are deprecated; use @gen_test instead.

class tornado.testing.AsyncHTTPTestCase(methodName: str = 'runTest')

A test case that starts up an HTTP server.

Subclasses must override get_app(), which returns the tornado.web.Application (or other HTTPServer
callback) to be tested. Tests will typically use the provided self.http_client to fetch URLs from this server.

Example, assuming the “Hello, world” example from the user guide is in hello.py:

import hello
class TestHelloApp(AsyncHTTPTestCase):
    def get_app(self):
        return hello.make_app()

    def test_homepage(self):
        response = self.fetch('/')

6.7. Utilities 155
That call to `self.fetch()` is equivalent to

```python
self.http_client.fetch(self.get_url('/'), self.stop)
response = self.wait()
```

which illustrates how `AsyncTestCase` can turn an asynchronous operation, like `http_client.fetch()`, into a synchronous operation. If you need to do other asynchronous operations in tests, you’ll probably need to use `stop()` and `wait()` yourself.

### get_app() → Application

Should be overridden by subclasses to return a `tornado.web.Application` or other `HTTPServer` callback.

### fetch(path: str, raise_error: bool = False, **kwargs: Any) → HTTPResponse

Convenience method to synchronously fetch a URL.

The given path will be appended to the local server’s host and port. Any additional keyword arguments will be passed directly to `AsyncHTTPClient.fetch` (and so could be used to pass `method="POST", body=".."`, etc).

- If the path begins with `http://` or `https://`, it will be treated as a full URL and will be fetched as-is.
- If `raise_error` is True, a `tornado.httpclient.HTTPError` will be raised if the response code is not 200. This is the same behavior as the `raise_error` argument to `AsyncHTTPClient.fetch`, but the default is False here (it’s True in `AsyncHTTPClient`) because tests often need to deal with non-200 response codes.

  - Changed in version 5.0: Added support for absolute URLs.
  - Changed in version 5.1: Added the `raise_error` argument.

- Deprecated since version 5.1: This method currently turns any exception into an `HTTPResponse` with status code 599. In Tornado 6.0, errors other than `tornado.httpclient.HTTPError` will be passed through, and `raise_error=False` will only suppress errors that would be raised due to non-200 response codes.

### get_httpserver_options() → Dict[str, Any]

May be overridden by subclasses to return additional keyword arguments for the server.

### get_http_port() → int

Returns the port used by the server.

A new port is chosen for each test.

### get_url(path: str) → str

Returns an absolute url for the given path on the test server.

### class tornado.testing.AsyncHTTPSTestCase(methodName: str = 'runTest')

A test case that starts an HTTPS server.

Interface is generally the same as `AsyncHTTPTestCase`.

### get_ssl_options() → Dict[str, Any]

May be overridden by subclasses to select SSL options.

By default includes a self-signed testing certificate.
tornado.testing.gen_test(*, timeout: Optional[float] = None) → Callable[[Callable[...], Union[Generator, Coroutine]], Callable[[...], None]]

Testing equivalent of @gen.coroutine, to be applied to test methods.

@gen.coroutine cannot be used on tests because the IOLoop is not already running. @gen_test should be applied to test methods on subclasses of AsyncTestCase.

Example:

class MyTest(AsyncHTTPTestCase):
    @gen_test
    def test_something(self):
        response = yield self.http_client.fetch(self.get_url('/'))

By default, @gen_test times out after 5 seconds. The timeout may be overridden globally with the ASYNC_TEST_TIMEOUT environment variable, or for each test with the timeout keyword argument:

class MyTest(AsyncHTTPTestCase):
    @gen_test(timeout=10)
    def test_something_slow(self):
        response = yield self.http_client.fetch(self.get_url('/'))

Note that @gen_test is incompatible with AsyncTestCase.stop, AsyncTestCase.wait, and AsyncHTTPTestCase.fetch. Use yield self.http_client.fetch(self.get_url()) as shown above instead.

New in version 3.1: The timeout argument and ASYNC_TEST_TIMEOUT environment variable.

Changed in version 4.0: The wrapper now passes along *args, **kwargs so it can be used on functions with arguments.

Controlling log output

class tornado.testing.ExpectLog(logger: Union[Logger, str], regex: str, required: bool = True, level: Optional[int] = None)

Context manager to capture and suppress expected log output.

Useful to make tests of error conditions less noisy, while still leaving unexpected log entries visible. Not thread safe.

The attribute logged_stack is set to True if any exception stack trace was logged.

Usage:

with ExpectLog('tornado.application', 'Uncaught exception'):
    error_response = self.fetch('/some_page')

Changed in version 4.3: Added the logged_stack attribute.

Constructs an ExpectLog context manager.

Parameters

- **logger** – Logger object (or name of logger) to watch. Pass an empty string to watch the root logger.
- **regex** – Regular expression to match. Any log entries on the specified logger that match this regex will be suppressed.
• **required** – If true, an exception will be raised if the end of the `with` statement is reached without matching any log entries.

• **level** – A constant from the `logging` module indicating the expected log level. If this parameter is provided, only log messages at this level will be considered to match. Additionally, the supplied `logger` will have its level adjusted if necessary (for the duration of the `ExpectLog` to enable the expected message.

Changed in version 6.1: Added the `level` parameter.

Deprecated since version 6.3: In Tornado 7.0, only `WARNING` and higher logging levels will be matched by default. To match `INFO` and lower levels, the `level` argument must be used. This is changing to minimize differences between `tornado.testing.main` (which enables `INFO` logs by default) and most other test runners (including those in IDEs) which have `INFO` logs disabled by default.

### Test runner

**tornado.testing.main(**\**kwargs: Any) \rightarrow None**

A simple test runner.

This test runner is essentially equivalent to `unittest.main` from the standard library, but adds support for Tornado-style option parsing and log formatting. It is *not* necessary to use this `main` function to run tests using `AsyncTestCase`; these tests are self-contained and can run with any test runner.

The easiest way to run a test is via the command line:

```
python -m tornado.testing tornado.test.web_test
```

See the standard library `unittest` module for ways in which tests can be specified.

Projects with many tests may wish to define a test script like `tornado/test/runtests.py`. This script should define a method `all()` which returns a test suite and then call `tornado.testing.main()`. Note that even when a test script is used, the `all()` test suite may be overridden by naming a single test on the command line:

```
# Runs all tests
python -m tornado.test.runtests
# Runs one test
python -m tornado.test.runtests tornado.test.web_test
```

Additional keyword arguments passed through to `unittest.main()`. For example, use `tornado.testing.main(verbosity=2)` to show many test details as they are run. See [http://docs.python.org/library/unittest.html#unittest.main](http://docs.python.org/library/unittest.html#unittest.main) for full argument list.

Changed in version 5.0: This function produces no output of its own; only that produced by the `unittest` module (previously it would add a PASS or FAIL log message).

### Helper functions

**tornado.testing.bind_unused_port**(\*\*\*`kwargs: Any) \rightarrow Tuple[socket, int]

Binds a server socket to an available port on localhost.

Returns a tuple (socket, port).

Changed in version 4.4: Always binds to `127.0.0.1` without resolving the name `localhost`.

Changed in version 6.2: Added optional `address` argument to override the default “127.0.0.1”.
tornado.testing.get_async_test_timeout() → float

Get the global timeout setting for async tests.
Returns a float, the timeout in seconds.
New in version 3.1.

6.7.6 tornado.util — General-purpose utilities

Miscellaneous utility functions and classes.
This module is used internally by Tornado. It is not necessarily expected that the functions and classes defined here will be useful to other applications, but they are documented here in case they are.
The one public-facing part of this module is the Configurable class and its configure method, which becomes a part of the interface of its subclasses, including AsyncHTTPClient, IOLoop, and Resolver.

class tornado.util.TimeoutError

Exception raised by gen.with_timeout and IOLoop.run_sync.
Changed in version 5.0: Unified tornado.gen.TimeoutError and tornado.ioloop.TimeoutError as tornado.util.TimeoutError. Both former names remain as aliases.
Changed in version 6.2: tornado.util.TimeoutError is an alias to asyncio.TimeoutError

class tornado.util.ObjectDict

Makes a dictionary behave like an object, with attribute-style access.

class tornado.util.GzipDecompressor

Streaming gzip decompressor.
The interface is like that of zlib.decompressobj (without some of the optional arguments, but it understands gzip headers and checksums.

decompress(value: bytes, max_length: int = 0) → bytes

Decompress a chunk, returning newly-available data.
Some data may be buffered for later processing; flush must be called when there is no more input data to ensure that all data was processed.
If max_length is given, some input data may be left over in unconsumed_tail; you must retrieve this value and pass it back to a future call to decompress if it is not empty.

property unconsumed_tail: bytes

Returns the unconsumed portion left over

flush() → bytes

Return any remaining buffered data not yet returned by decompress.
Also checks for errors such as truncated input. No other methods may be called on this object after flush.

tornado.util.import_object(name: str) → Any

Imports an object by name.
import_object('x') is equivalent to import x. import_object('x.y.z') is equivalent to from x.y import z.
```python
>>> import tornado.escape
>>> import_object('tornado.escape') is tornado.escape
True
>>> import_object('tornado.escape.utf8') is tornado.escape.utf8
True
>>> import_object('tornado') is tornado
True
>>> import_object('tornado.missing_module')
Traceback (most recent call last):
...
ImportError: No module named missing_module
```

tornado.util.erro_from_exception(e: BaseException) → Optional[int]

Provides the errno from an Exception object.

There are cases that the errno attribute was not set so we pull the errno out of the args but if someone instantiates an Exception without any args you will get a tuple error. So this function abstracts all that behavior to give you a safe way to get the errno.

tornado.util.re_unescape(s: str) → str

Unescape a string escaped by re.escape.

May raise ValueError for regular expressions which could not have been produced by re.escape (for example, strings containing \d cannot be unescaped).

New in version 4.4.

class tornado.util.Configurable(*args: Any, **kwargs: Any)

Base class for configurable interfaces.

A configurable interface is an (abstract) class whose constructor acts as a factory function for one of its implementation subclasses. The implementation subclass as well as optional keyword arguments to its initializer can be set globally at runtime with configure.

By using the constructor as the factory method, the interface looks like a normal class, isinstance works as usual, etc. This pattern is most useful when the choice of implementation is likely to be a global decision (e.g. when epoll is available, always use it instead of select), or when a previously-monolithic class has been split into specialized subclasses.

Configurable subclasses must define the class methods configurable_base and configurable_default, and use the instance method initialize instead of __init__.

Changed in version 5.0: It is now possible for configuration to be specified at multiple levels of a class hierarchy.

classmethod configurable_base() → Type[Configurable]

Returns the base class of a configurable hierarchy.

This will normally return the class in which it is defined. (which is not necessarily the same as the cls classmethod parameter).

classmethod configurable_default() → Type[Configurable]

Returns the implementation class to be used if none is configured.

initialize() → None

Initialize a Configurable subclass instance.

Configurable classes should use initialize instead of __init__.

Changed in version 4.2: Now accepts positional arguments in addition to keyword arguments.
classmethod configure(impl: Union[None, str, Type[Configurable]], **kwags: Any) → None

Sets the class to use when the base class is instantiated.

Keyword arguments will be saved and added to the arguments passed to the constructor. This can be used to set global defaults for some parameters.

classmethod configured_class() → Type[Configurable]

Returns the currently configured class.

class tornado.util.ArgReplacer(func: Callable, name: str)

Replaces one value in an args, kwargs pair.

Inspects the function signature to find an argument by name whether it is passed by position or keyword. For use in decorators and similar wrappers.

get_old_value(args: Sequence[Any], kwargs: Dict[str, Any], default: Optional[Any] = None) → Any

Returns the old value of the named argument without replacing it.

Returns default if the argument is not present.

replace(new_value: Any, args: Sequence[Any], kwargs: Dict[str, Any]) → Tuple[Any, Sequence[Any], Dict[str, Any]]

Replace the named argument in args, kwargs with new_value.

Returns (old_value, args, kwargs). The returned args and kwargs objects may not be the same as the input objects, or the input objects may be mutated.

If the named argument was not found, new_value will be added to kwargs and None will be returned as old_value.

tornado.util.timedelta_to_seconds(td: datetime.timedelta) → float

Equivalent to td.total_seconds() (introduced in Python 2.7).

6.8 Frequently Asked Questions

- Why isn’t this example with time.sleep() running in parallel?
- My code is asynchronous. Why is it not running in parallel in two browser tabs?

6.8.1 Why isn’t this example with time.sleep() running in parallel?

Many people’s first foray into Tornado’s concurrency looks something like this:

class BadExampleHandler(RequestHandler):  
    def get(self):
        for i in range(5):
            print(i)
            time.sleep(1)

Fetch this handler twice at the same time and you’ll see that the second five-second countdown doesn’t start until the first one has completely finished. The reason for this is that time.sleep is a blocking function: it doesn’t allow control to return to the IOLoop so that other handlers can be run.
Of course, \texttt{time.sleep} is really just a placeholder in these examples, the point is to show what happens when something in a handler gets slow. No matter what the real code is doing, to achieve concurrency blocking code must be replaced with non-blocking equivalents. This means one of three things:

1. **Find a coroutine-friendly equivalent.** For \texttt{time.sleep}, use \texttt{tornado.gen.sleep} (or \texttt{asyncio.sleep}) instead:

   ```python
   class CoroutineSleepHandler(RequestHandler):
       async def get(self):
           for i in range(5):
               print(i)
               await gen.sleep(1)
   ```

   When this option is available, it is usually the best approach. See the Tornado wiki for links to asynchronous libraries that may be useful.

2. **Find a callback-based equivalent.** Similar to the first option, callback-based libraries are available for many tasks, although they are slightly more complicated to use than a library designed for coroutines. Adapt the callback-based function into a future:

   ```python
   class CoroutineTimeoutHandler(RequestHandler):
       async def get(self):
           io_loop = IOLoop.current()
           for i in range(5):
               print(i)
               f = tornado.concurrent.Future()
               do_something_with_callback(f.set_result)
               result = await f
   ```

   Again, the Tornado wiki can be useful to find suitable libraries.

3. **Run the blocking code on another thread.** When asynchronous libraries are not available, \texttt{concurrent.futures.ThreadPoolExecutor} can be used to run any blocking code on another thread. This is a universal solution that can be used for any blocking function whether an asynchronous counterpart exists or not:

   ```python
   class ThreadPoolHandler(RequestHandler):
       async def get(self):
           for i in range(5):
               print(i)
               await IOLoop.current().run_in_executor(None, time.sleep, 1)
   ```

See the Asynchronous I/O chapter of the Tornado user’s guide for more on blocking and asynchronous functions.

### 6.8.2 My code is asynchronous. Why is it not running in parallel in two browser tabs?

Even when a handler is asynchronous and non-blocking, it can be surprisingly tricky to verify this. Browsers will recognize that you are trying to load the same page in two different tabs and delay the second request until the first has finished. To work around this and see that the server is in fact working in parallel, do one of two things:

- Add something to your urls to make them unique. Instead of \texttt{http://localhost:8888} in both tabs, load \texttt{http://localhost:8888/?x=1} in one and \texttt{http://localhost:8888/?x=2} in the other.
- Use two different browsers. For example, Firefox will be able to load a url even while that same url is being loaded in a Chrome tab.
6.9 Release notes

6.9.1 What’s new in Tornado 6.3.2

May 13, 2023

Security improvements

• Fixed an open redirect vulnerability in StaticFileHandler under certain configurations.

6.9.2 What’s new in Tornado 6.3.1

Apr 21, 2023

tornado.web

• RequestHandler.set_cookie once again accepts capitalized keyword arguments for backwards compatibility. This is deprecated and in Tornado 7.0 only lowercase arguments will be accepted.

6.9.3 What’s new in Tornado 6.3.0

Apr 17, 2023

Highlights

• The new Application setting xsrf_cookie_name can now be used to take advantage of the __Host cookie prefix for improved security. To use it, add {"xsrf_cookie_name": "__Host-xsrf", "xsrf_cookie_kwars": {"secure": True}} to your Application settings. Note that this feature currently only works when HTTPS is used.

• WSGIContainer now supports running the application in a ThreadPoolExecutor so the event loop is no longer blocked.

• AsyncTestCase and AsyncHTTPTestCase, which were deprecated in Tornado 6.2, are no longer deprecated.

• WebSockets are now much faster at receiving large messages split into many fragments.

General changes

• Python 3.7 is no longer supported; the minimum supported Python version is 3.8. Python 3.12 is now supported.

• To avoid spurious deprecation warnings, users of Python 3.10 should upgrade to at least version 3.10.9, and users of Python 3.11 should upgrade to at least version 3.11.1.

• Tornado submodules are now imported automatically on demand. This means it is now possible to use a single import tornado statement and refer to objects in submodules such as tornado.web.RequestHandler.
Deprecation notices

• In Tornado 7.0, `tornado.testing.ExpectLog` will match `WARNING` and above regardless of the current logging configuration, unless the `level` argument is used.

• `RequestHandler.get_secure_cookie` is now a deprecated alias for `RequestHandler.get_signed_cookie`. `RequestHandler.set_secure_cookie` is now a deprecated alias for `RequestHandler.set_signed_cookie`.

• `RequestHandler.clear_all_cookies` is deprecated. No direct replacement is provided; `RequestHandler.clear_cookie` should be used on individual cookies.

• Calling the `IOLoop` constructor without a `make_current` argument, which was deprecated in Tornado 6.2, is no longer deprecated.

• `AsyncTestCase` and `AsyncHTTPTestCase`, which were deprecated in Tornado 6.2, are no longer deprecated.

• `AsyncTestCase.get_new_ioloop` is deprecated.

`tornado.auth`

• New method `GoogleOAuth2Mixin.get_google_oauth_settings` can now be overridden to get credentials from a source other than the `Application` settings.

`tornado.gen`

• `contextvars` now work properly when a `@gen.coroutine` calls a native coroutine.

`tornado.options`

• `parse_config_file` now recognizes single comma-separated strings (in addition to lists of strings) for options with `multiple=True`.

`tornado.web`

• New `Application` setting `xsrf_cookie_name` can be used to change the name of the XSRF cookie. This is most useful to take advantage of the `__Host-` cookie prefix.

• `RequestHandler.get_secure_cookie` and `RequestHandler.set_secure_cookie` (and related methods and attributes) have been renamed to `get_signed_cookie` and `set_signed_cookie`. This makes it more explicit what kind of security is provided, and avoids confusion with the `Secure` cookie attribute and `__Secure-` cookie prefix. The old names remain supported as deprecated aliases.

• `RequestHandler.clear_cookie` now accepts all keyword arguments accepted by `set_cookie`. In some cases clearing a cookie requires certain arguments to be passed the same way in which it was set.

• `RequestHandler.clear_all_cookies` now accepts additional keyword arguments for the same reason as `clear_cookie`. However, since the requirements for additional arguments mean that it cannot reliably clear all cookies, this method is now deprecated.
**tornado.websocket**

- It is now much faster (no longer quadratic) to receive large messages that have been split into many fragments.
- `websocket_connect` now accepts a `resolver` parameter.

**tornado.wsgi**

- `WSGIContainer` now accepts an `executor` parameter which can be used to run the WSGI application on a thread pool.

### 6.9.4 What’s new in Tornado 6.2.0

**Jul 3, 2022**

**Deprecation notice**

- April 2023 update: Python 3.12 reversed some of the changes described below. In Tornado 6.3, `AsyncTestCase`, `AsyncHTTPTestCase`, and the behavior of the `IOLoop` constructor related to the `make_current` parameter are no longer deprecated.

- Python 3.10 has begun the process of significant changes to the APIs for managing the event loop. Calls to methods such as `asyncio.get_event_loop` may now raise `DeprecationWarning` if no event loop is running. This has significant impact on the patterns for initializing applications, and in particular invalidates patterns that have long been the norm in Tornado’s documentation and actual usage. In the future (with some as-yet-unspecified future version of Python), the old APIs will be removed. The new recommended pattern is to start the event loop with `asyncio.run`. More detailed migration guides will be coming in the future.
  - The `IOLoop` constructor is deprecated unless the `make_current=False` argument is used. Use `IOLoop.current` when the loop is already running instead.
  - `AsyncTestCase` (and `AsyncHTTPTestCase`) are deprecated. Use `unittest.IsolatedAsyncioTestCase` instead.
  - Multi-process `TCPServer.bind/TCPServer.start` is deprecated. See `TCPServer` docs for supported alternatives.
  - `AnyThreadEventLoopPolicy` is deprecated. This class controls the creation of the “current” event loop so it will be removed when that concept is no longer supported.
  - `IOLoop.make_current` and `IOLoop.clear_current` are deprecated. In the future the concept of a “current” event loop as distinct from one that is currently running will be removed.

- `TwistedResolver` and `CaresResolver` are deprecated and will be removed in Tornado 7.0.
General changes

- The minimum supported Python version is now 3.7.
- Wheels are now published with the Python stable ABI (abi3) for compatibility across versions of Python.
- SSL certificate verification and hostname checks are now enabled by default in more places (primarily in client-side usage of SSLIOStream).
- Various improvements to type hints throughout the package.
- CI has moved from Travis and Appveyor to Github Actions.

**tornado.gen**

- Fixed a bug in which WaitIterator.current_index could be incorrect.
- `tornado.gen.TimeoutError` is now an alias for `asyncio.TimeoutError`.

**tornado.http1connection**

- `max_body_size` may now be set to zero to disallow a non-empty body.
- Content-Encoding: gzip is now recognized case-insensitively.

**tornado.httpclient**

- `curl_httpclient` now supports non-ASCII (ISO-8859-1) header values, same as `simple_httpclient`.

**tornado.ioloop**

- `PeriodicCallback` now understands coroutines and will not start multiple copies if a previous invocation runs too long.
- `PeriodicCallback` now accepts `datetime.timedelta` objects in addition to numbers of milliseconds.
- Avoid logging “Event loop is closed” during shutdown-related race conditions.
- Tornado no longer calls `logging.basicConfig` when starting an IOLoop; this has been unnecessary since Python 3.2 added a logger of last resort.
- The `IOLoop` constructor now accepts an `asyncio_loop` keyword argument to initialize with a specified asyncio event loop.
- It is now possible to construct an `IOLoop` on one thread (with `make_current=False`) and start it on a different thread.
tornado.iostream

- **SSLIOStream** now supports reading more than 2GB at a time.
- **IOStream.write** now supports typed `memoryview` objects.

tornado.locale

- **load_gettext_translations** no longer logs errors when language directories exist but do not contain the expected file.

tornado.netutil

- **is_valid_ip** no longer raises exceptions when the input is too long.
- The default resolver now uses the same methods (and thread pool) as **asyncio**.

tornado.tcpserver

- **TCPServer.listen** now supports more arguments to pass through to **netutil.bind_sockets**.

tornado.testing

- **bind_unused_port** now takes an optional **address** argument.
- Wrapped test methods now include the `__wrapped__` attribute.

tornado.web

- When using a custom **StaticFileHandler** subclass, the **reset()** method is now called on this subclass instead of the base class.
- Improved handling of the **Accept-Language** header.
- **Application.listen** now supports more arguments to pass through to **netutil.bind_sockets**.

tornado.websocket

- **WebSocketClientConnection.write_message** now accepts `dict` arguments for consistency with **WebSocketHandler.write_message**.
- **WebSocketClientConnection.write_message** now raises an exception as documented if the connection is already closed.
6.9.5 What’s new in Tornado 6.1.0

Oct 30, 2020

Deprecation notice

• This is the last release of Tornado to support Python 3.5. Future versions will require Python 3.6 or newer.

General changes

• Windows support has been improved. Tornado is now compatible with the proactor event loop (which became the default in Python 3.8) by automatically falling back to running a selector in a second thread. This means that it is no longer necessary to explicitly configure a selector event loop, although doing so may improve performance. This does not change the fact that Tornado is significantly less scalable on Windows than on other platforms.

• Binary wheels are now provided for Windows, MacOS, and Linux (amd64 and arm64).

tornado.gen

• coroutine now has better support for the Python 3.7+ contextvars module. In particular, the ContextVar.reset method is now supported.

tornado.http1connection

• HEAD requests to handlers that used chunked encoding no longer produce malformed output.

• Certain kinds of malformed gzip data no longer cause an infinite loop.

tornado.httpclient

• Setting decompress_response=False now works correctly with curl_httpclient.

• Mixing requests with and without proxies works correctly in curl_httpclient (assuming the version of pycurl is recent enough).

• A default User-Agent of Tornado/$VERSION is now used if the user_agent parameter is not specified.

• After a 303 redirect, tornado.simple_httpclient always uses GET. Previously this would use GET if the original request was a POST and would otherwise reuse the original request method. For curl_httpclient, the behavior depends on the version of libcurl (with the most recent versions using GET after 303 regardless of the original method).

• Setting request_timeout and/or connect_timeout to zero is now supported to disable the timeout.
tornado.httputil

- Header parsing is now faster.
- `parse_body_arguments` now accepts incompletely-escaped non-ASCII inputs.

---

tornado.iostream

- `ssl.CertificateError` during the SSL handshake is now handled correctly.
- Reads that are resolved while the stream is closing are now handled correctly.

---

tornado.log

- When colored logging is enabled, `logging.CRITICAL` messages are now recognized and colored magenta.

---

tornado.netutil

- `EADDRNOTAVAIL` is now ignored when binding to `localhost` with IPv6. This error is common in docker.

---

tornado.platform.asyncio

- `AnyThreadEventLoopPolicy` now also configures a selector event loop for these threads (the proactor event loop only works on the main thread)

---

tornado.platform.auto

- The `set_close_exec` function has been removed.

---

tornado.testing

- `ExpectLog` now has a `level` argument to ensure that the given log level is enabled.

---

tornado.web

- `RedirectHandler.get` now accepts keyword arguments.
- When sending 304 responses, more headers (including `Allow`) are now preserved.
- `reverse_url` correctly handles escaped characters in the regex route.
- Default `Etag` headers are now generated with SHA-512 instead of MD5.
tornado.websocket

- The `ping_interval` timer is now stopped when the connection is closed.
- `websocket_connect` now raises an error when it encounters a redirect instead of hanging.

### 6.9.6 What's new in Tornado 6.0.4

Mar 3, 2020

**General changes**

- Binary wheels are now available for Python 3.8 on Windows. Note that it is still necessary to use `asyncio.set_event_loop_policy(asyncio.WindowsSelectorEventLoopPolicy())` for this platform/version.

**Bug fixes**

- Fixed an issue in `IOStream` (introduced in 6.0.0) that resulted in `StreamClosedError` being incorrectly raised if a stream is closed mid-read but there is enough buffered data to satisfy the read.
- `AnyThreadEventLoopPolicy` now always uses the selector event loop on Windows.

### 6.9.7 What's new in Tornado 6.0.3

Jun 22, 2019

**Bug fixes**

- `gen.with_timeout` always treats `asyncio.CancelledError` as a `quiet_exception` (this improves compatibility with Python 3.8, which changed `CancelledError` to a `BaseException`).
- `IOStream` now checks for closed streams earlier, avoiding spurious logged errors in some situations (mainly with websockets).

### 6.9.8 What's new in Tornado 6.0.2

Mar 23, 2019

**Bug fixes**

- `WebSocketHandler.set_nodelay` works again.
- Accessing `HTTPResponse.body` now returns an empty byte string instead of raising `ValueError` for error responses that don’t have a body (it returned `None` in this case in Tornado 5).
6.9.9 What’s new in Tornado 6.0.1

Mar 3, 2019

Bug fixes

• Fixed issues with type annotations that caused errors while importing Tornado on Python 3.5.2.

6.9.10 What’s new in Tornado 6.0

Mar 1, 2019

Backwards-incompatible changes

• Python 2.7 and 3.4 are no longer supported; the minimum supported Python version is 3.5.2.
• APIs deprecated in Tornado 5.1 have been removed. This includes the `tornado.stack_context` module and most callback arguments throughout the package. All removed APIs emitted `DeprecationWarning` when used in Tornado 5.1, so running your application with the `-Wd` Python command-line flag or the environment variable `PYTHONWARNINGS=d` should tell you whether your application is ready to move to Tornado 6.0.
• `.WebSocketHandler.get` is now a coroutine and must be called accordingly in any subclasses that override this method (but note that overriding `get` is not recommended; either `prepare` or `open` should be used instead).

General changes

• Tornado now includes type annotations compatible with `mypy`. These annotations will be used when type-checking your application with `mypy`, and may be usable in editors and other tools.
• Tornado now uses native coroutines internally, improving performance.

`tornado.auth`

• All callback arguments in this package have been removed. Use the coroutine interfaces instead.
• The `OAuthMixin._oauth_get_user` method has been removed. Override `_oauth_get_user_future` instead.

`tornado.concurrent`

• The callback argument to `run_on_executor` has been removed.
• `return_future` has been removed.
tornado.gen

- Some older portions of this module have been removed. This includes `engine`, `YieldPoint`, `Callback`, `Wait`, `WaitAll`, `MultiYieldPoint`, and `Task`.
- Functions decorated with `@gen.coroutine` no longer accept `callback` arguments.

tornado.httpclient

- The behavior of `raise_error=False` has changed. Now only suppresses the errors raised due to completed responses with non-200 status codes (previously it suppressed all errors).
- The `callback` argument to `AsyncHTTPClient.fetch` has been removed.

tornado.httputil

- `HTTPServerRequest.write` has been removed. Use the methods of `request.connection` instead.
- Unrecognized `Content-Encoding` values now log warnings only for content types that we would otherwise attempt to parse.

tornado.ioloop

- `IOLoop.set_blocking_signal_threshold`, `IOLoop.set_blocking_log_threshold`, `IOLoop.log_stack`, and `IOLoop.handle_callback_exception` have been removed.
- Improved performance of `IOLoop.add_callback`.

tornado.iostream

- All callback arguments in this module have been removed except for `BaseIOStream.set_close_callback`.
- `streaming_callback` arguments to `BaseIOStream.read_bytes` and `BaseIOStream.read_until_close` have been removed.
- Eliminated unnecessary logging of “Errno 0”.

tornado.log

- Log files opened by this module are now explicitly set to UTF-8 encoding.

tornado.netutil

- The results of `getaddrinfo` are now sorted by address family to avoid partial failures and deadlocks.
tornado.platform.twisted

- TornadoReactor and TwistedIOLoop have been removed.

tornado.simple_httpclient

- The default HTTP client now supports the `network_interface` request argument to specify the source IP for the connection.
- If a server returns a 3xx response code without a Location header, the response is raised or returned directly instead of trying and failing to follow the redirect.
- When following redirects, methods other than POST will no longer be transformed into GET requests. 301 (permanent) redirects are now treated the same way as 302 (temporary) and 303 (see other) redirects in this respect.
- Following redirects now works with `body_producer`.

tornado.stack_context

- The `tornado.stack_context` module has been removed.

tornado.tcpserver

- `TCPServer.start` now supports a `max_restarts` argument (same as `fork_processes`).

tornado.testing

- `AsyncHTTPTestCase` now drops all references to the `Application` during `tearDown`, allowing its memory to be reclaimed sooner.
- `AsyncTestCase` now cancels all pending coroutines in `tearDown`, in an effort to reduce warnings from the python runtime about coroutines that were not awaited. Note that this may cause `asyncio.CancelledError` to be logged in other places. Coroutines that expect to be running at test shutdown may need to catch this exception.

tornado.web

- The asynchronous decorator has been removed.
- The callback argument to `RequestHandler.flush` has been removed.
- `StaticFileHandler` now supports large negative values for the `Range` header and returns an appropriate error for `end > start`.
- It is now possible to set `expires_days` in `xsrf_cookie_kwargs`.
tornado.websocket

- Pings and other messages sent while the connection is closing are now silently dropped instead of logging exceptions.
- Errors raised by open() are now caught correctly when this method is a coroutine.

tornado.wsgi

- WSGIApplication and WSGIAdapter have been removed.

6.9.11 What’s new in Tornado 5.1.1

Sep 16, 2018

Bug fixes

- Fixed a case in which the Future returned by RequestHandler.finish could fail to resolve.
- The TwitterMixin.authenticate_redirect method works again.
- Improved error handling in the tornado.auth module, fixing hanging requests when a network or other error occurs.

6.9.12 What’s new in Tornado 5.1

July 12, 2018

Deprecation notice

- Tornado 6.0 will drop support for Python 2.7 and 3.4. The minimum supported Python version will be 3.5.2.
- The tornado.stack_context module is deprecated and will be removed in Tornado 6.0. The reason for this is that it is not feasible to provide this module’s semantics in the presence of async def native coroutines. ExceptionStackContext is mainly obsolete thanks to coroutines. StackContext lacks a direct replacement although the new contextvars package (in the Python standard library beginning in Python 3.7) may be an alternative.
- Callback-oriented code often relies on ExceptionStackContext to handle errors and prevent leaked connections. In order to avoid the risk of silently introducing subtle leaks (and to consolidate all of Tornado’s interfaces behind the coroutine pattern), callback arguments throughout the package are deprecated and will be removed in version 6.0. All functions that had a callback argument removed now return a Future which should be used instead.
- Where possible, deprecation warnings are emitted when any of these deprecated interfaces is used. However, Python does not display deprecation warnings by default. To prepare your application for Tornado 6.0, run Python with the -Wd argument or set the environment variable PYTHONWARNINGS to d. If your application runs on Python 3 without deprecation warnings, it should be able to move to Tornado 6.0 without disruption.
**tornado.auth**

- `OAuthMixin._oauth_get_user_future` may now be a native coroutine.
- All callback arguments in this package are deprecated and will be removed in 6.0. Use the coroutine interfaces instead.
- The `OAuthMixin._oauth_get_user` method is deprecated and will be removed in 6.0. Override `_oauth_get_user_future` instead.

**tornado.autoreload**

- The command-line autoreload wrapper is now preserved if an internal autoreload fires.
- The command-line wrapper no longer starts duplicated processes on windows when combined with internal autoreload.

**tornado.concurrent**

- `run_on_executor` now returns `Future` objects that are compatible with `await`.
- The callback argument to `run_on_executor` is deprecated and will be removed in 6.0.
- `return_future` is deprecated and will be removed in 6.0.

**tornado.gen**

- Some older portions of this module are deprecated and will be removed in 6.0. This includes `engine`, `YieldPoint`, `Callback`, `Wait`, `WaitAll`, `MultiYieldPoint`, and `Task`.
- Functions decorated with `@gen.coroutine` will no longer accept callback arguments in 6.0.

**tornado.httpclient**

- The behavior of `raise_error=False` is changing in 6.0. Currently it suppresses all errors; in 6.0 it will only suppress the errors raised due to completed responses with non-200 status codes.
- The callback argument to `AsyncHTTPClient.fetch` is deprecated and will be removed in 6.0.
- `tornado.httpclient.HTTPError` has been renamed to `HTTPClientError` to avoid ambiguity in code that also has to deal with `tornado.web.HTTPError`. The old name remains as an alias.
- `tornado.curl_httpclient` now supports non-ASCII characters in username and password arguments.
- `.HTTPResponse.request_time` now behaves consistently across `simple_httpclient` and `curl_httpclient`, excluding time spent in the `max_clients` queue in both cases (previously this time was included in `simple_httpclient` but excluded in `curl_httpclient`). In both cases the time is now computed using a monotonic clock where available.
- `.HTTPResponse` now has a `start_time` attribute recording a wall-clock (time.time) timestamp at which the request started (after leaving the `max_clients` queue if applicable).
tornado.httputil

- `parse_multipart_form_data` now recognizes non-ASCII filenames in RFC 2231/5987 (`filename*=`) format.
- `HTTPServerRequest.write` is deprecated and will be removed in 6.0. Use the methods of `request.connection` instead.
- Malformed HTTP headers are now logged less noisily.

tornado.ioloop

- `PeriodicCallback` now supports a `jitter` argument to randomly vary the timeout.
- `IOLoop.set_blocking_signal_threshold`, `IOLoop.set_blocking_log_threshold`, `IOLoop.log_stack`, and `IOLoop.handle_callback_exception` are deprecated and will be removed in 6.0.
- Fixed a `KeyError` in `IOLoop.close` when `IOLoop` objects are being opened and closed in multiple threads.

tornado.iostream

- All callback arguments in this module are deprecated except for `BaseIOStream.set_close_callback`. They will be removed in 6.0.
- `streaming_callback` arguments to `BaseIOStream.read_bytes` and `BaseIOStream.read_until_close` are deprecated and will be removed in 6.0.

tornado.netutil

- Improved compatibility with GNU Hurd.

tornado.options

- `tornado.options.parse_config_file` now allows setting options to strings (which will be parsed the same way as `tornado.options.parse_command_line`) in addition to the specified type for the option.

tornado.platform.twisted

- `TornadoReactor` and `TwistedIOLoop` are deprecated and will be removed in 6.0. Instead, Tornado will always use the asyncio event loop and twisted can be configured to do so as well.
tornado.stack_context

- The `tornado.stack_context` module is deprecated and will be removed in 6.0.

tornado.testing

- `AsyncHTTPTestCase.fetch` now takes a `raise_error` argument. This argument has the same semantics as `AsyncHTTPClient.fetch`, but defaults to false because tests often need to deal with non-200 responses (and for backwards-compatibility).
- The `AsyncTestCase.stop` and `AsyncTestCase.wait` methods are deprecated.

tornado.web

- New method `RequestHandler.detach` can be used from methods that are not decorated with `@asynchronous` (the decorator was required to use `self.request.connection.detach()`).
- `RequestHandler.finish` and `RequestHandler.render` now return Futures that can be used to wait for the last part of the response to be sent to the client.
- `FallbackHandler` now calls `on_finish` for the benefit of subclasses that may have overridden it.
- The `asynchronous` decorator is deprecated and will be removed in 6.0.
- The `callback` argument to `RequestHandler.flush` is deprecated and will be removed in 6.0.

tornado.websocket

- When compression is enabled, memory limits now apply to the post-decompression size of the data, protecting against DoS attacks.
- `websocket_connect` now supports subprotocols.
- `WebSocketHandler` and `WebSocketClientConnection` now have `selected_subprotocol` attributes to see the subprotocol in use.
- The `WebSocketHandler.select_subprotocol` method is now called with an empty list instead of a list containing an empty string if no subprotocols were requested by the client.
- `WebSocketHandler.open` may now be a coroutine.
- The `data` argument to `WebSocketHandler.ping` is now optional.
- Client-side websocket connections no longer buffer more than one message in memory at a time.
- Exception logging now uses `RequestHandler.log_exception`.
tornado.wsgi

- WSGIApplication and WSGIAdapter are deprecated and will be removed in Tornado 6.0.

## 6.9.13 What’s new in Tornado 5.0.2

### Apr 7, 2018

**Bug fixes**

- Fixed a memory leak when `IOLoop` objects are created and destroyed.
- If `AsyncTestCase.get_new_ioloop` returns a reference to a preexisting event loop (typically when it has been overridden to return `IOLoop.current()`), the test’s `tearDown` method will not close this loop.
- Fixed a confusing error message when the synchronous `HTTPClient` fails to initialize because an event loop is already running.
- `PeriodicCallback` no longer executes twice in a row due to backwards clock adjustments.

## 6.9.14 What’s new in Tornado 5.0.1

### Mar 18, 2018

**Bug fix**

- This release restores support for versions of Python 3.4 prior to 3.4.4. This is important for compatibility with Debian Jessie which has 3.4.2 as its version of Python 3.

## 6.9.15 What’s new in Tornado 5.0

### Mar 5, 2018

**Highlights**

- The focus of this release is improving integration with `asyncio`. On Python 3, the `IOLoop` is always a wrapper around the `asyncio` event loop, and `asyncio.Future` and `asyncio.Task` are used instead of their Tornado counterparts. This means that libraries based on `asyncio` can be mixed relatively seamlessly with those using Tornado. While care has been taken to minimize the disruption from this change, code changes may be required for compatibility with Tornado 5.0, as detailed in the following section.
- Tornado 5.0 supports Python 2.7.9+ and 3.4+. Python 2.7 and 3.4 are deprecated and support for them will be removed in Tornado 6.0, which will require Python 3.5+. 
Backwards-compatibility notes

- Python 3.3 is no longer supported.
- Versions of Python 2.7 that predate the `ssl` module update are no longer supported. (The `ssl` module was updated in version 2.7.9, although in some distributions the updates are present in builds with a lower version number. Tornado requires `ssl.SSLContext`, `ssl.create_default_context`, and `ssl.match_hostname`)
- Versions of Python 3.5 prior to 3.5.2 are no longer supported due to a change in the async iterator protocol in that version.
- The `trollius` project (asyncio backported to Python 2) is no longer supported.
- `tornado.concurrent.Future` is now an alias for `asyncio.Future` when running on Python 3. This results in a number of minor behavioral changes:
  - `Future` objects can only be created while there is a current `IOLoop`
  - The timing of callbacks scheduled with `Future.add_done_callback` has changed. `tornado.concurrent.future_add_done_callback` can be used to make the behavior more like older versions of Tornado (but not identical). Some of these changes are also present in the Python 2 version of `tornado.concurrent.Future` to minimize the difference between Python 2 and 3.
  - Cancellation is now partially supported, via `asyncio.Future.cancel`. A canceled `Future` can no longer have its result set. Applications that handle `Future` objects directly may want to use `tornado.concurrent.future_set_result_unless_cancelled`. In native coroutines, cancellation will cause an exception to be raised in the coroutine.
  - The `exc_info` and `set_exc_info` methods are no longer present. Use `tornado.concurrent.future_set_exc_info` to replace the latter, and raise the exception with `result` to replace the former.
- `io_loop` arguments to many Tornado functions have been removed. Use `IOLoop.current()` instead of passing `IOLoop` objects explicitly.
- On Python 3, `IOLoop` is always a wrapper around the `asyncio` event loop. `IOLoop.configure` is effectively removed on Python 3 (for compatibility, it may be called to redundantly specify the asyncio-backed `IOLoop`)
- `IOLoop.instance` is now a deprecated alias for `IOLoop.current`. Applications that need the cross-thread communication behavior facilitated by `IOLoop.instance` should use their own global variable instead.

Other notes

- The `futures` (`concurrent.futures` backport) package is now required on Python 2.7.
- The `certifi` and backports.ssl-match-hostname packages are no longer required on Python 2.7.
- Python 3.6 or higher is recommended, because it features more efficient garbage collection of `asyncio.Future` objects.
tornado.auth

- `GoogleOAuth2Mixin` now uses a newer set of URLs.

**tornado.autoreload**

- On Python 3, uses `__main__.__spec` to more reliably reconstruct the original command line and avoid modifying PYTHONPATH.
- The `io_loop` argument to `tornado.autoreload.start` has been removed.

**tornado.concurrent**

- Setting the result of a Future no longer blocks while callbacks are being run. Instead, the callbacks are scheduled on the next `IOLoop` iteration.
- The deprecated alias `tornado.concurrent.TracebackFuture` has been removed.
- `tornado.concurrent.chain_future` now works with all three kinds of Futures (Tornado, asyncio, and `concurrent.futures`)
- The `io_loop` argument to `tornado.concurrent.run_on_executor` has been removed.
- New functions `future_set_result_unless_cancelled`, `future_set_exc_info`, and `future_add_done_callback` help mask the difference between `asyncio.Future` and Tornado’s previous Future implementation.

**tornado.curl_httpclient**

- Improved debug logging on Python 3.
- The `time_info` response attribute now includes `appconnect` in addition to other measurements.
- Closing a `CurlAsyncHTTPClient` now breaks circular references that could delay garbage collection.
- The `io_loop` argument to the `CurlAsyncHTTPClient` constructor has been removed.

**tornado.gen**

- `tornado.gen.TimeoutError` is now an alias for `tornado.util.TimeoutError`.
- Leak detection for Futures created by this module now attributes them to their proper caller instead of the coroutine machinery.
- Several circular references that could delay garbage collection have been broken up.
- On Python 3, `asyncio.Task` is used instead of the Tornado coroutine runner. This improves compatibility with some `asyncio` libraries and adds support for cancellation.
- The `io_loop` arguments to `YieldFuture` and `with_timeout` have been removed.
tornado.httpclient

- The io_loop argument to all AsyncHTTPClient constructors has been removed.

tornado.httpserver

- It is now possible for a client to reuse a connection after sending a chunked request.
- If a client sends a malformed request, the server now responds with a 400 error instead of simply closing the connection.
- Content-Length and Transfer-Encoding headers are no longer sent with 1xx or 204 responses (this was already true of 304 responses).
- When closing a connection to a HTTP/1.1 client, the Connection: close header is sent with the response.
- The io_loop argument to the HTTPServer constructor has been removed.
- If more than one X-Scheme or X-Forwarded-Proto header is present, only the last is used.

tornado.httputil

- The string representation of HTTPServerRequest objects (which are sometimes used in log messages) no longer includes the request headers.
- New function qs_to_qsl converts the result of urllib.parse.parse_qs to name-value pairs.

tornado.ioloop

- tornado.ioloop.TimeoutError is now an alias for tornado.util.TimeoutError.
- IOLoop.instance is now a deprecated alias for IOLoop.current.
- IOLoop.install and IOLoop.clear_instance are deprecated.
- The IOLoop.initialized method has been removed.
- On Python 3, the asyncio-backed IOLoop is always used and alternative IOLoop implementations cannot be configured. IOLoop.current and related methods pass through to asyncio.get_event_loop.
- run_sync cancels its argument on a timeout. This results in better stack traces (and avoids log messages about leaks) in native coroutines.
- New methods IOLoop.run_in_executor and IOLoop.set_default_executor make it easier to run functions in other threads from native coroutines (since concurrent.futures.Future does not support await).
- PollIOLoop (the default on Python 2) attempts to detect misuse of IOLoop instances across os.fork.
- The io_loop argument to PeriodicCallback has been removed.
- It is now possible to create a PeriodicCallback in one thread and start it in another without passing an explicit event loop.
- The IOLoop.set_blocking_signal_threshold and IOLoop.set_blocking_log_threshold methods are deprecated because they are not implemented for the asyncio event loop. Use the PYTHONASYNCIODEBUG=1 environment variable instead.
- IOLoop.clear_current now works if it is called before any current loop is established.
**tornado.iostream**

- The `io_loop` argument to the `IOStream` constructor has been removed.
- New method `BaseIOStream.read_into` provides a minimal-copy alternative to `BaseIOStream.read_bytes`.
- `BaseIOStream.write` is now much more efficient for very large amounts of data.
- Fixed some cases in which `IOStream.error` could be inaccurate.
- Writing a `memoryview` can no longer result in “BufferError: Existing exports of data: object cannot be re-sized”.

**tornado.locks**

- As a side effect of the `Future` changes, waiters are always notified asynchronously with respect to `Condition.notify`.

**tornado.netutil**

- The default `Resolver` now uses `IOLoop.run_in_executor. ExecutorResolver, BlockingResolver, and ThreadedResolver` are deprecated.
- The `io_loop` arguments to `add_accept_handler`, `ExecutorResolver`, and `ThreadedResolver` have been removed.
  - `add_accept_handler` returns a callable which can be used to remove all handlers that were added.
  - `OverrideResolver` now accepts per-family overrides.

**tornado.options**

- Duplicate option names are now detected properly whether they use hyphens or underscores.

**tornado.platform.asyncio**

- `AsyncIOLoop` and `AsyncIOMainLoop` are now used automatically when appropriate; referencing them explicitly is no longer recommended.
- Starting an `IOLoop` or making it current now also sets the `asyncio` event loop for the current thread. Closing an `IOLoop` closes the corresponding `asyncio` event loop.
- `to_tornado_future` and `to_asyncio_future` are deprecated since they are now no-ops.
- `AnyThreadEventLoopPolicy` can now be used to easily allow the creation of event loops on any thread (similar to Tornado’s prior policy).
tornado.platform.caresresolver

- The io_loop argument to `CaresResolver` has been removed.

tornado.platform.twisted

- The io_loop arguments to `TornadoReactor`, `TwistedResolver`, and `tornado.platform.twisted.install` have been removed.

tornado.process

- The io_loop argument to the `Subprocess` constructor and `Subprocess.initialize` has been removed.

tornado.routing

- A default 404 response is now generated if no delegate is found for a request.

tornado.simple_httpclient

- The io_loop argument to `SimpleAsyncHTTPClient` has been removed.
- TLS is now configured according to `ssl.create_default_context` by default.

tornado.tcpclient

- The io_loop argument to the `TCPClient` constructor has been removed.
- `TCPClient.connect` has a new `timeout` argument.

tornado.tcpserver

- The io_loop argument to the `TCPServer` constructor has been removed.
- `TCPServer` no longer logs EBADF errors during shutdown.

tornado.testing

- The deprecated `tornado.testing.get_unused_port` and `tornado.testing.LogTrapTestCase` have been removed.
- `AsyncHTTPTestCase.fetch` now supports absolute URLs.
- `AsyncHTTPTestCase.fetch` now connects to `127.0.0.1` instead of localhost to be more robust against faulty ipv6 configurations.
tornado.util

• `Configurable` now supports configuration at multiple levels of an inheritance hierarchy.

tornado.web

• `RequestHandler.set_status` no longer requires that the given status code appear in `http.client.responses`.
• It is no longer allowed to send a body with 1xx or 204 responses.
• Exception handling now breaks up reference cycles that could delay garbage collection.
• `RedirectHandler` now copies any query arguments from the request to the redirect location.
• If both `If-None-Match` and `If-Modified-Since` headers are present in a request to `StaticFileHandler`, the latter is now ignored.

tornado.websocket

• The C accelerator now operates on multiple bytes at a time to improve performance.
• Requests with invalid websocket headers now get a response with status code 400 instead of a closed connection.
• `WebSocketHandler.write_message` now raises `WebSocketClosedError` if the connection closes while the write is in progress.
• The `io_loop` argument to `websocket_connect` has been removed.

6.9.16 What’s new in Tornado 4.5.3

Jan 6, 2018

tornado.curl_httpclient

• Improved debug logging on Python 3.

tornado.httpserver

• `Content-Length` and `Transfer-Encoding` headers are no longer sent with 1xx or 204 responses (this was already true of 304 responses).
• Reading chunked requests no longer leaves the connection in a broken state.
tornado.iostream

- Writing a `memoryview` can no longer result in “BufferError: Existing exports of data: object cannot be re-sized”.

tornado.options

- Duplicate option names are now detected properly whether they use hyphens or underscores.

tornado.testing

- `AsyncHTTPTestCase.fetch` now uses `127.0.0.1` instead of `localhost`, improving compatibility with systems that have partially-working ipv6 stacks.

tornado.web

- It is no longer allowed to send a body with 1xx or 204 responses.

tornado.websocket

- Requests with invalid websocket headers now get a response with status code 400 instead of a closed connection.

6.9.17 What’s new in Tornado 4.5.2

Aug 27, 2017

Bug Fixes

- Tornado now sets the FD_CLOEXEC flag on all file descriptors it creates. This prevents hanging client connections and resource leaks when the `tornado.autoreload` module (or `Application(debug=True)`) is used.

6.9.18 What’s new in Tornado 4.5.1

Apr 20, 2017

tornado.log

- Improved detection of libraries for colorized logging.
tornado.httputil

- `url_concat` once again treats None as equivalent to an empty sequence.

### 6.9.19 What’s new in Tornado 4.5

**Apr 16, 2017**

**Backwards-compatibility warning**

- The `tornado.websocket` module now imposes a limit on the size of incoming messages, which defaults to 10MiB.

**New module**

- `tornado.routing` provides a more flexible routing system than the one built in to `Application`.

**General changes**

- Reduced the number of circular references, reducing memory usage and improving performance.

**tornado.auth**

- The `tornado.auth` module has been updated for compatibility with a change to Facebook’s `access_token` endpoint. This includes both the changes initially released in Tornado 4.4.3 and an additional change to support the `session_expires` field in the new format. The `session_expires` field is currently a string; it should be accessed as `int(user['session_expires'])` because it will change from a string to an int in Tornado 5.0.

**tornado.autoreload**

- Autoreload is now compatible with the `asyncio` event loop.
- Autoreload no longer attempts to close the `IOLoop` and all registered file descriptors before restarting; it relies on the `CLOEXEC` flag being set instead.

**tornado.concurrent**

- Suppressed some “‘NoneType’ object not callback” messages that could be logged at shutdown.
tornado.gen

- `yield None` is now equivalent to `yield gen.moment`. `moment` is deprecated. This improves compatibility with asyncio.
- Fixed an issue in which a generator object could be garbage collected prematurely (most often when weak references are used).
- New function `is_coroutine_function` identifies functions wrapped by `coroutine` or `engine`.

tornado.http1connection

- The `Transfer-Encoding` header is now parsed case-insensitively.

tornado.httpclient

- `SimpleAsyncHTTPClient` now follows 308 redirects.
- `CurlAsyncHTTPClient` will no longer accept protocols other than `http` and `https`. To override this, set `pycurl.PROTOCOLS` and `pycurl.REDIR_PROTOCOLS` in a `prepare_curl_callback`.
- `CurlAsyncHTTPClient` now supports digest authentication for proxies (in addition to basic auth) via the new `proxy_auth_mode` argument.
- The minimum supported version of `libcurl` is now 7.22.0.

tornado.httpserver

- `HTTPServer` now accepts the keyword argument `trusted_downstream` which controls the parsing of `X-Forwarded-For` headers. This header may be a list or set of IP addresses of trusted proxies which will be skipped in the `X-Forwarded-For` list.
- The `no_keep_alive` argument works again.

tornado.httputil

- `url_concat` correctly handles fragments and existing query arguments.

tornado.ioloop

- Fixed 100% CPU usage after a callback returns an empty list or dict.
- `IOLoop.add_callback` now uses a lockless implementation which makes it safe for use from `__del__` methods. This improves performance of calls to `add_callback` from the `IOLoop` thread, and slightly decreases it for calls from other threads.
tornado.iostream

- memoryview objects are now permitted as arguments to write.
- The internal memory buffers used by IOStream now use bytearray instead of a list of bytes, improving performance.
- Futures returned by write are no longer orphaned if a second call to write occurs before the previous one is finished.

tornado.log

- Colored log output is now supported on Windows if the colorama library is installed and the application calls colorama.init() at startup.
- The signature of the LogFormatter constructor has been changed to make it compatible with logging.config.dictConfig.

tornado.netutil

- Worked around an issue that caused “LookupError: unknown encoding: latin1” errors on Solaris.

tornado.process

- Subprocess no longer causes “subprocess still running” warnings on Python 3.6.
- Improved error handling in cpu_count.

tornado.tcpclient

- TCPClient now supports a source_ip and source_port argument.
- Improved error handling for environments where IPv6 support is incomplete.

tornado.tcpserver

- TCPServer.handle_stream implementations may now be native coroutines.
- Stopping a TCPServer twice no longer raises an exception.

tornado.web

- RedirectHandler now supports substituting parts of the matched URL into the redirect location using str.format syntax.
- New methods RequestHandler.render_linked_js, RequestHandler.render_embed_js, RequestHandler.render_linked_css, and RequestHandler.render_embed_css can be overridden to customize the output of UIModule.
**tornado.websocket**

- `WebSocketHandler.on_message` implementations may now be coroutines. New messages will not be processed until the previous `on_message` coroutine has finished.
- The `websocket_ping_interval` and `websocket_ping_timeout` application settings can now be used to enable a periodic ping of the websocket connection, allowing dropped connections to be detected and closed.
- The new `websocket_max_message_size` setting defaults to 10MiB. The connection will be closed if messages larger than this are received.
- Headers set by `RequestHandler.prepare` or `RequestHandler.set_default_headers` are now sent as a part of the websocket handshake.
- Return values from `WebSocketHandler.get_compression_options` may now include the keys `compression_level` and `mem_level` to set gzip parameters. The default compression level is now 6 instead of 9.

**Demos**

- A new file upload demo is available in the `file_upload` directory.
- A new `TCPClient` and `TCPServer` demo is available in the `tcpecho` directory.
- Minor updates have been made to several existing demos, including updates to more recent versions of jquery.

6.9.20 What’s new in Tornado 4.4.3

Mar 30, 2017

Bug fixes

- The tornado.auth module has been updated for compatibility with a change to Facebook’s access_token endpoint.
6.9.21 What’s new in Tornado 4.4.2

Oct 1, 2016

Security fixes

- A difference in cookie parsing between Tornado and web browsers (especially when combined with Google Analytics) could allow an attacker to set arbitrary cookies and bypass XSRF protection. The cookie parser has been rewritten to fix this attack.

Backwards-compatibility notes

- Cookies containing certain special characters (in particular semicolon and square brackets) are now parsed differently.
- If the cookie header contains a combination of valid and invalid cookies, the valid ones will be returned (older versions of Tornado would reject the entire header for a single invalid cookie).

6.9.22 What’s new in Tornado 4.4.1

Jul 23, 2016

tornado.web

- Fixed a regression in Tornado 4.4 which caused URL regexes containing backslash escapes outside capturing groups to be rejected.

6.9.23 What’s new in Tornado 4.4

Jul 15, 2016

General

- Tornado now requires Python 2.7 or 3.3+; versions 2.6 and 3.2 are no longer supported. Pypy3 is still supported even though its latest release is mainly based on Python 3.2.
- The monotonic package is now supported as an alternative to Monotime for monotonic clock support on Python 2.

tornado.curl_httpclient

- Failures in _curl_setup_request no longer cause the max_clients pool to be exhausted.
- Non-ascii header values are now handled correctly.
tornado.gen

- `with_timeout` now accepts any yieldable object (except `YieldPoint`), not just `tornado.concurrent.Future`.

**tornado.httpclient**

- The errors raised by timeouts now indicate what state the request was in; the error message is no longer simply “599 Timeout”.
- Calling `repr` on a `tornado.httpclient.HTTPError` no longer raises an error.

**tornado.httpserver**

- Int-like enums (including `http.HTTPStatus`) can now be used as status codes.
- Responses with status code 204 No Content no longer emit a `Content-Length: 0` header.

**tornado.ioloop**

- Improved performance when there are large numbers of active timeouts.

**tornado.netutil**

- All included `Resolver` implementations raise `IOError` (or a subclass) for any resolution failure.

**tornado.options**

- Options can now be modified with subscript syntax in addition to attribute syntax.
- The special variable `__file__` is now available inside config files.

**tornado.simple_httpclient**

- HTTP/1.0 (not 1.1) responses without a `Content-Length` header now work correctly.

**tornado.tcpserver**

- `TCPServer.bind` now accepts a `reuse_port` argument.
tornado.testing

- Test sockets now always use `127.0.0.1` instead of `localhost`. This avoids conflicts when the automatically-assigned port is available on IPv4 but not IPv6, or in unusual network configurations when `localhost` has multiple IP addresses.

tornado.web

- `image/svg+xml` is now on the list of compressible mime types.
- Fixed an error on Python 3 when compression is used with multiple Vary headers.

tornado.websocket

- `WebSocketHandler.__init__` now uses `super`, which improves support for multiple inheritance.

6.9.24 What’s new in Tornado 4.3

Nov 6, 2015

Highlights

- The new async/await keywords in Python 3.5 are supported. In most cases, `async def` can be used in place of the `@gen.coroutine` decorator. Inside a function defined with `async def`, use `await` instead of `yield` to wait on an asynchronous operation. Coroutines defined with async/await will be faster than those defined with `@gen.coroutine` and `yield`, but do not support some features including Callback/Wait or the ability to yield a Twisted Deferred. See the users' guide for more.
- The async/await keywords are also available when compiling with Cython in older versions of Python.

Deprecation notice

- This will be the last release of Tornado to support Python 2.6 or 3.2. Note that PyPy3 will continue to be supported even though it implements a mix of Python 3.2 and 3.3 features.

Installation

- Tornado has several new dependencies: `ordereddict` on Python 2.6, `singledispatch` on all Python versions prior to 3.4 (This was an optional dependency in prior versions of Tornado, and is now mandatory), and `backports_abc>=0.4` on all versions prior to 3.5. These dependencies will be installed automatically when installing with `pip` or `setup.py install`. These dependencies will not be required when running on Google App Engine.
- Binary wheels are provided for Python 3.5 on Windows (32 and 64 bit).
tornado.auth

- New method `OAuth2Mixin.oauth2_request` can be used to make authenticated requests with an access token.
- Now compatible with callbacks that have been compiled with Cython.

tornado.autoreload

- Fixed an issue with the autoreload command-line wrapper in which imports would be incorrectly interpreted as relative.

tornado.curl_httpclient

- Fixed parsing of multi-line headers.
- `allow_nonstandard_methods=True` now bypasses body sanity checks, in the same way as in `simple_httpclient`.
- The PATCH method now allows a body without `allow_nonstandard_methods=True`.

tornado.gen

- `WaitIterator` now supports the `async for` statement on Python 3.5.
- `@gen.coroutine` can be applied to functions compiled with Cython. On python versions prior to 3.5, the `backports_abc` package must be installed for this functionality.
- `Multi` and `multi_future` are deprecated and replaced by a unified function `multi`.

tornado.httpclient

- `tornado.httpclient.HTTPError` is now copyable with the `copy` module.

tornado.httpserver

- Requests containing both `Content-Length` and `Transfer-Encoding` will be treated as an error.

tornado.httputil

- `HTTPHeaders` can now be pickled and unpickled.
tornado.ioloop

- `IOLoop(make_current=True)` now works as intended instead of raising an exception.
- The Twisted and asyncio IOLoop implementations now clear `current()` when they exit, like the standard IOLoops.
- `IOLoop.add_callback` is faster in the single-threaded case.
- `IOLoop.add_callback` no longer raises an error when called on a closed IOLoop, but the callback will not be invoked.

 tornado.iostream

- Coroutine-style usage of `IOStream` now converts most errors into `StreamClosedError`, which has the effect of reducing log noise from exceptions that are outside the application’s control (especially SSL errors).
- `StreamClosedError` now has a `real_error` attribute which indicates why the stream was closed. It is the same as the `error` attribute of `IOStream` but may be more easily accessible than the `IOStream` itself.
- Improved error handling in `read_until_close`.
- Logging is less noisy when an SSL server is port scanned.
- EINTR is now handled on all reads.

 tornado.locale

- `tornado.locale.load_translations` now accepts encodings other than UTF-8. UTF-16 and UTF-8 will be detected automatically if a BOM is present; for other encodings `load_translations` has an `encoding` parameter.

 tornado.locks

- `Lock` and `Semaphore` now support the `async with` statement on Python 3.5.

 tornado.log

- A new time-based log rotation mode is available with `--log_rotate_mode=time`, `--log_rotate_when`, and `log_rotate_interval`.

 tornado.netutil

- `bind_sockets` now supports `SO_REUSEPORT` with the `reuse_port=True` argument.
tornado.options

- Dashes and underscores are now fully interchangeable in option names.

tornado.queues

- `Queue` now supports the `async for` statement on Python 3.5.

tornado.simple_httpclient

- When following redirects, `streaming_callback` and `header_callback` will no longer be run on the redirect responses (only the final non-redirect).
- Responses containing both `Content-Length` and `Transfer-Encoding` will be treated as an error.

tornado.template

- `tornado.template.ParseError` now includes the filename in addition to line number.
- Whitespace handling has become more configurable. The `Loader` constructor now has a `whitespace` argument, there is a new `template_whitespace` `Application` setting, and there is a new `{% whitespace %}` template directive. All of these options take a mode name defined in the `tornado.template.filter_whitespace` function. The default mode is `single`, which is the same behavior as prior versions of Tornado.
- Non-ASCII filenames are now supported.

tornado.testing

- `ExpectLog` objects now have a boolean `logged_stack` attribute to make it easier to test whether an exception stack trace was logged.

tornado.web

- The hard limit of 4000 bytes per outgoing header has been removed.
- `StaticFileHandler` returns the correct `Content-Type` for files with `.gz`, `.bz2`, and `.xz` extensions.
- Responses smaller than 1000 bytes will no longer be compressed.
- The default gzip compression level is now 6 (was 9).
- Fixed a regression in Tornado 4.2.1 that broke `StaticFileHandler` with a path of `/.`.
- `tornado.web.HTTPError` is now copyable with the `copy` module.
- The exception `Finish` now accepts an argument which will be passed to the method `RequestHandler.finish`.
- New `Application` setting `xsrf_cookie_kwargs` can be used to set additional attributes such as `secure` or `httponly` on the XSRF cookie.
- `Application.listen` now returns the `HTTPServer` it created.
**tornado.websocket**

- Fixed handling of continuation frames when compression is enabled.

### 6.9.25 What’s new in Tornado 4.2.1

**Jul 17, 2015**

**Security fix**

- This release fixes a path traversal vulnerability in `StaticFileHandler`, in which files whose names started with the `static_path` directory but were not actually in that directory could be accessed.

### 6.9.26 What’s new in Tornado 4.2

**May 26, 2015**

**Backwards-compatibility notes**

- `SSLIOStream.connect` and `IOLStream.start_tls` now validate certificates by default.
- Certificate validation will now use the system CA root certificates instead of `certifi` when possible (i.e. Python 2.7.9+ or 3.4+). This includes `IOLStream` and `simple_httpclient`, but not `curl_httpclient`.
- The default SSL configuration has become stricter, using `ssl.create_default_context` where available on the client side. (On the server side, applications are encouraged to migrate from the `ssl_options` dict-based API to pass an `ssl.SSLContext` instead).
- The deprecated classes in the `tornado.auth` module, `GoogleMixin`, `FacebookMixin`, and `FriendFeedMixin` have been removed.

**New modules: `tornado.locks` and `tornado.queues`**

These modules provide classes for coordinating coroutines, merged from `Toro`.

To port your code from Toro’s queues to Tornado 4.2, import `Queue`, `PriorityQueue`, or `LifoQueue` from `tornado.queues` instead of from `toro`.

Use `Queue` instead of Toro’s `JoinableQueue`. In Tornado the methods `join` and `task_done` are available on all queues, not on a special `JoinableQueue`.

Tornado queues raise exceptions specific to Tornado instead of reusing exceptions from the Python standard library. Therefore instead of catching the standard `queue.Empty` exception from `Queue.get_nowait`, catch the special `tornado.queues.QueueEmpty` exception, and instead of catching the standard `queue.Full` from `Queue.get_nowait`, catch `tornado.queues.QueueFull`.

To port from Toro’s locks to Tornado 4.2, import `Condition`, `Event`, `Semaphore`, `BoundedSemaphore`, or `Lock` from `tornado.locks` instead of from `toro`.

Toro’s `Semaphore.wait` allowed a coroutine to wait for the semaphore to be unlocked without acquiring it. This encouraged unorthodox patterns; in Tornado, just use `acquire`.

Toro’s `Event.wait` raised a `Timeout` exception after a timeout. In Tornado, `Event.wait` raises `tornado.gen.TimeoutError`.
Toro’s `Condition.wait` also raised `Timeout`, but in Tornado, the `Future` returned by `Condition.wait` resolves to `False` after a timeout:

```python
@gen.coroutine
def await_notification():
    if not (yield condition.wait(timeout=timedelta(seconds=1))):
        print('timed out')
    else:
        print('condition is true')
```

In lock and queue methods, wherever Toro accepted `deadline` as a keyword argument, Tornado names the argument `timeout` instead.

Toro’s `AsyncResult` is not merged into Tornado, nor its exceptions `NotReady` and `AlreadySet`. Use a `Future` instead. If you wrote code like this:

```python
from tornado import gen
import toro

result = toro.AsyncResult()

@gen.coroutine
def setter():
    result.set(1)

@gen.coroutine
def getter():
    value = yield result.get()
    print(value)  # Prints "1".
```

Then the Tornado equivalent is:

```python
from tornado import gen
from tornado.concurrent import Future

result = Future()

@gen.coroutine
def setter():
    result.set_result(1)

@gen.coroutine
def getter():
    value = yield result
    print(value)  # Prints "1".
```
tornado.autoreload

- Improved compatibility with Windows.
- Fixed a bug in Python 3 if a module was imported during a reload check.

tornado.concurrent

- `run_on_executor` now accepts arguments to control which attributes it uses to find the `IOLoop` and executor.

tornado.curl_httpclient

- Fixed a bug that would cause the client to stop processing requests if an exception occurred in certain places while there is a queue.

tornado.escape

- `xhtml_escape` now supports numeric character references in hex format (`&#x20;`)

tornado.gen

- `WaitIterator` no longer uses weak references, which fixes several garbage-collection-related bugs.
- `tornado.gen.Multi` and `tornado.gen.multi_future` (which are used when yielding a list or dict in a coroutine) now log any exceptions after the first if more than one `Future` fails (previously they would be logged when the `Future` was garbage-collected, but this is more reliable). Both have a new keyword argument `quiet_exceptions` to suppress logging of certain exception types; to use this argument you must call `Multi` or `multi_future` directly instead of simply yielding a list.
- `multi_future` now works when given multiple copies of the same `Future`.
- On Python 3, catching an exception in a coroutine no longer leads to leaks via `Exception.__context__`.

_tornado.httpclient

- The `raise_error` argument now works correctly with the synchronous `HTTPClient`.
- The synchronous `HTTPClient` no longer interferes with `IOLoop.current()`.

_tornado.httpserver

- `HTTPServer` is now a subclass of `tornado.util.Configurable`. 
tornado.httputil

- *HTTPHeaders* can now be copied with *copy.copy* and *copy.deepcopy*.

tornado.ioloop

- The *IOLoop* constructor now has a *make_current* keyword argument to control whether the new *IOLoop* becomes *IOLoop.current()*.
- Third-party implementations of *IOLoop* should accept **kwargs in their *IOLoop.initialize* methods and pass them to the superclass implementation.
- *PeriodicCallback* is now more efficient when the clock jumps forward by a large amount.

tornado.iostream

- *SSLIOStream.connect* and *IOStream.start_tls* now validate certificates by default.
- New method *SSLIOStream.wait_for_handshake* allows server-side applications to wait for the handshake to complete in order to verify client certificates or use NPN/ALPN.
- The *Future* returned by *SSLIOStream.connect* now resolves after the handshake is complete instead of as soon as the TCP connection is established.
- Reduced logging of SSL errors.
- *BaseIOStream.read_until_close* now works correctly when a *streaming_callback* is given but callback is None (i.e. when it returns a *Future*)

tornado.locale

- New method *GettextLocale.pgettext* allows additional context to be supplied for gettext translations.

tornado.log

- *define_logging_options* now works correctly when given a non-default *options* object.

tornado.process

- New method *Subprocess.wait_for_exit* is a coroutine-friendly version of *Subprocess.set_exit_callback*. 
**tornado.simple_httpclient**

- Improved performance on Python 3 by reusing a single `ssl.SSLContext`.
- New constructor argument `max_body_size` controls the maximum response size the client is willing to accept. It may be bigger than `max_buffer_size` if `streaming_callback` is used.

**tornado.tcpserver**

- `TCPServer.handle_stream` may be a coroutine (so that any exceptions it raises will be logged).

**tornado.util**

- `import_object` now supports unicode strings on Python 2.
- `Configurable.initialize` now supports positional arguments.

**tornado.web**

- Key versioning support for cookie signing. `cookie_secret` application setting can now contain a dict of valid keys with version as key. The current signing key then must be specified via `key_version` setting.
- Parsing of the `If-None-Match` header now follows the RFC and supports weak validators.
- Passing `secure=False` or `httponly=False` to `RequestHandler.set_cookie` now works as expected (previously only the presence of the argument was considered and its value was ignored).
- `RequestHandler.get_arguments` now requires that its `strip` argument be of type bool. This helps prevent errors caused by the slightly dissimilar interfaces between the singular and plural methods.
- Errors raised in `_handle_request_exception` are now logged more reliably.
- `RequestHandler.redirect` now works correctly when called from a handler whose path begins with two slashes.
- Passing messages containing `%` characters to `tornado.web.HTTPError` no longer causes broken error messages.

**tornado.websocket**

- The `on_close` method will no longer be called more than once.
- When the other side closes a connection, we now echo the received close code back instead of sending an empty close frame.
6.9.27 What's new in Tornado 4.1

Feb 7, 2015

Highlights

- If a `Future` contains an exception but that exception is never examined or re-raised (e.g. by yielding the `Future`), a stack trace will be logged when the `Future` is garbage-collected.
- New class `tornado.gen.WaitIterator` provides a way to iterate over `Futures` in the order they resolve.
- The `tornado.websocket` module now supports compression via the “permessage-deflate” extension. Override `WebSocketHandler.get_compression_options` to enable on the server side, and use the `compression_options` keyword argument to `websocket_connect` on the client side.
- When the appropriate packages are installed, it is possible to yield `asyncio.Future` or Twisted `Deferred` objects in Tornado coroutines.

Backwards-compatibility notes

- `HTTPServer` now calls `start_request` with the correct arguments. This change is backwards-incompatible, affecting any application which implemented `HTTPServerConnectionDelegate` by following the example of `Application` instead of the documented method signatures.

`tornado.concurrent`

- If a `Future` contains an exception but that exception is never examined or re-raised (e.g. by yielding the `Future`), a stack trace will be logged when the `Future` is garbage-collected.
- `Future` now catches and logs exceptions in its callbacks.

`tornado.curl_httpclient`

- `tornado.curl_httpclient` now supports request bodies for PATCH and custom methods.
- `tornado.curl_httpclient` now supports resubmitting bodies after following redirects for methods other than POST.
- `curl_httpclient` now runs the streaming and header callbacks on the IOLoop.
- `tornado.curl_httpclient` now uses its own logger for debug output so it can be filtered more easily.

`tornado.gen`

- New class `tornado.gen.WaitIterator` provides a way to iterate over `Futures` in the order they resolve.
- When the `singledispatch` library is available (standard on Python 3.4, available via `pip install singledispatch` on older versions), the `convert_yielded` function can be used to make other kinds of objects yieldable in coroutines.
- New function `tornado.gen.sleep` is a coroutine-friendly analogue to `time.sleep`.
- `gen.engine` now correctly captures the stack context for its callbacks.
tornado.httpclient

- `tornado.httpclient.HTTPRequest` accepts a new argument `raise_error=False` to suppress the default behavior of raising an error for non-200 response codes.

tornado.httpserver

- `HTTPServer` now calls `start_request` with the correct arguments. This change is backwards-incompatible, affecting any application which implemented `HTTPServerConnectionDelegate` by following the example of `Application` instead of the documented method signatures.
- `HTTPServer` now tolerates extra newlines which are sometimes inserted between requests on keep-alive connections.
- `HTTPServer` can now use keep-alive connections after a request with a chunked body.
- `HTTPServer` now always reports `HTTP/1.1` instead of echoing the request version.

tornado.httputil

- New function `tornado.httputil.split_host_and_port` for parsing the `netloc` portion of URLs.
- The `context` argument to `HTTPServerRequest` is now optional, and if a context is supplied the `remote_ip` attribute is also optional.
- `HTTPServerRequest.body` is now always a byte string (previously the default empty body would be a unicode string on python 3).
- Header parsing now works correctly when newline-like unicode characters are present.
- Header parsing again supports both CRLF and bare LF line separators.
- Malformed `multipart/form-data` bodies will always be logged quietly instead of raising an unhandled exception; previously the behavior was inconsistent depending on the exact error.

tornado.ioloop

- The `kqueue` and `select` IOLoop implementations now report writeability correctly, fixing flow control in IOStream.
- When a new `IOLoop` is created, it automatically becomes “current” for the thread if there is not already a current instance.
- New method `PeriodicCallback.is_running` can be used to see whether the `PeriodicCallback` has been started.
### tornado.iostream

- `IOStream.start_tls` now uses the `server_hostname` parameter for certificate validation.
- `SSLIOStream` will no longer consume 100% CPU after certain error conditions.
- `SSLIOStream` no longer logs `EBADF` errors during the handshake as they can result from nmap scans in certain modes.

### tornado.options

- `parse_config_file` now always decodes the config file as utf8 on Python 3.
- `tornado.options.define` more accurately finds the module defining the option.

### tornado.platform.asyncio

- It is now possible to yield `asyncio.Future` objects in coroutines when the `singledispatch` library is available and `tornado.platform.asyncio` has been imported.
- New methods `tornado.platform.asyncio.to_tornado_future` and `to_asyncio_future` convert between the two libraries' `Future` classes.

### tornado.platform.twisted

- It is now possible to yield `Deferred` objects in coroutines when the `singledispatch` library is available and `tornado.platform.twisted` has been imported.

### tornado.tcpclient

- `TCPClient` will no longer raise an exception due to an ill-timed timeout.

### tornado.tcpserver

- `TCPServer` no longer ignores its `read_chunk_size` argument.

### tornado.testing

- `AsyncTestCase` has better support for multiple exceptions. Previously it would silently swallow all but the last; now it raises the first and logs all the rest.
- `AsyncTestCase` now cleans up `Subprocess` state on `tearDown` when necessary.
tornado.web

- The asynchronous decorator now understands `concurrent.futures.Future` in addition to `tornado.concurrent.Future`.
- `StaticFileHandler` no longer logs a stack trace if the connection is closed while sending the file.
- `RequestHandler.send_error` now supports a `reason` keyword argument, similar to `tornado.web.HTTPError`.
- `RequestHandler.locale` now has a property setter.
- `Application.add_handlers` hostname matching now works correctly with IPv6 literals.
- Redirects for the `Application default_host` setting now match the request protocol instead of redirecting HTTPS to HTTP.
- Malformed `_xsrf` cookies are now ignored instead of causing uncaught exceptions.
- `Application.start_request` now has the same signature as `HTTPServerConnectionDelegate.start_request`.

**tornado.websocket**

- The `tornado.websocket` module now supports compression via the “permessage-deflate” extension. Override `WebSocketHandler.get_compression_options` to enable on the server side, and use the `compression_options` keyword argument to `websocket_connect` on the client side.
- `WebSocketHandler` no longer logs stack traces when the connection is closed.
- `WebSocketHandler.open` now accepts `*args, **kw` for consistency with `RequestHandler.get` and related methods.
- The `Sec-WebSocket-Version` header now includes all supported versions.
- `websocket_connect` now has a `on_message_callback` keyword argument for callback-style use without `read_message()`.

### 6.9.28 What’s new in Tornado 4.0.2

**Sept 10, 2014**

**Bug fixes**

- Fixed a bug that could sometimes cause a timeout to fire after being cancelled.
- `AsyncTestCase` once again passes along arguments to test methods, making it compatible with extensions such as Nose’s test generators.
- `StaticFileHandler` can again compress its responses when gzip is enabled.
- `simple_httpclient` passes its `max_buffer_size` argument to the underlying stream.
- Fixed a reference cycle that can lead to increased memory consumption.
- `add_accept_handler` will now limit the number of times it will call `accept` per `IOLoop` iteration, addressing a potential starvation issue.
- Improved error handling in `IOLStream.connect` (primarily for FreeBSD systems)
6.9.29 What’s new in Tornado 4.0.1

Aug 12, 2014

- The build will now fall back to pure-python mode if the C extension fails to build for any reason (previously it would fall back for some errors but not others).
- `IOLoop.call_at` and `IOLoop.call_later` now always return a timeout handle for use with `IOLoop.remove_timeout`.
- If any callback of a `PeriodicCallback` or `IOStream` returns a `Future`, any error raised in that future will now be logged (similar to the behavior of `IOLoop.add_callback`).
- Fixed an exception in client-side websocket connections when the connection is closed.
- `simple_httpclient` once again correctly handles 204 status codes with no content-length header.
- Fixed a regression in `simple_httpclient` that would result in timeouts for certain kinds of errors.

6.9.30 What’s new in Tornado 4.0

July 15, 2014

Highlights

- The `tornado.web.stream_request_body` decorator allows large files to be uploaded with limited memory usage.
- Coroutines are now faster and are used extensively throughout Tornado itself. More methods now return `Futures`, including most `IOStream` methods and `RequestHandler.flush`.
- Many user-overridden methods are now allowed to return a `Future` for flow control.
- HTTP-related code is now shared between the `tornado.httpserver`, `tornado.simple_httpclient` and `tornado.wsgi` modules, making support for features such as chunked and gzip encoding more consistent. `HTTPServer` now uses new delegate interfaces defined in `tornado.httputil` in addition to its old single-callback interface.
- New module `tornado.tcpclient` creates TCP connections with non-blocking DNS, SSL handshaking, and support for IPv6.

Backwards-compatibility notes

- `tornado.concurrent.Future` is no longer thread-safe; use `concurrent.futures.Future` when thread-safety is needed.
- Tornado now depends on the `certifi` package instead of bundling its own copy of the Mozilla CA list. This will be installed automatically when using pip or `easy_install`.
- This version includes the changes to the secure cookie format first introduced in version 3.2.1, and the xsrf token change in version 3.2.2. If you are upgrading from an earlier version, see those versions’ release notes.
- WebSocket connections from other origin sites are now rejected by default. To accept cross-origin websocket connections, override the new method `WebSocketHandler.check_origin`.
- `WebSocketHandler` no longer supports the old draft 76 protocol (this mainly affects Safari 5.x browsers). Applications should use non-websocket workarounds for these browsers.
• Authors of alternative `IOLoop` implementations should see the changes to `IOLoop.add_handler` in this release.

• The `RequestHandler.async_callback` and `WebSocketHandler.async_callback` wrapper functions have been removed; they have been obsolete for a long time due to stack contexts (and more recently coroutines).

• `curl_httpclient` now requires a minimum of libcurl version 7.21.1 and pycurl 7.18.2.

• Support for `RequestHandler.get_error_html` has been removed; override `RequestHandler.write_error` instead.

Other notes

• The git repository has moved to https://github.com/tornadoweb/tornado. All old links should be redirected to the new location.

• An announcement mailing list is now available.

• All Tornado modules are now importable on Google App Engine (although the App Engine environment does not allow the system calls used by `IOLoop` so many modules are still unusable).

`tornado.auth`

• Fixed a bug in `.FacebookMixin` on Python 3.

• When using the `Future` interface, exceptions are more reliably delivered to the caller.

`tornado.concurrent`

• `tornado.concurrent.Future` is now always thread-unsafe (previously it would be thread-safe if the `concurrent.futures` package was available). This improves performance and provides more consistent semantics. The parts of Tornado that accept Futures will accept both Tornado’s thread-unsafe Futures and the thread-safe `concurrent.futures.Future`.

• `tornado.concurrent.Future` now includes all the functionality of the old `TracebackFuture` class. `TracebackFuture` is now simply an alias for `Future`.

`tornado.curl_httpclient`

• `curl_httpclient` now passes along the HTTP “reason” string in `response.reason`.

`tornado.gen`

• Performance of coroutines has been improved.

• Coroutines no longer generate `StackContexts` by default, but they will be created on demand when needed.

• The internals of the `tornado.gen` module have been rewritten to improve performance when using Futures, at the expense of some performance degradation for the older `YieldPoint` interfaces.

• New function `with_timeout` wraps a `Future` and raises an exception if it doesn’t complete in a given amount of time.

• New object `moment` can be yielded to allow the IOLoop to run for one iteration before resuming.
• Task is now a function returning a Future instead of a YieldPoint subclass. This change should be transparent to application code, but allows Task to take advantage of the newly-optimized Future handling.

tornado.http1connection

• New module contains the HTTP implementation shared by tornado.httpserver and tornado.simple_httpclient.

tornado.httpclient

• The command-line HTTP client (python -m tornado.httpclient $URL) now works on Python 3.
• Fixed a memory leak in AsyncHTTPClient shutdown that affected applications that created many HTTP clients and IOLoops.
• New client request parameter decompress_response replaces the existing use_gzip parameter; both names are accepted.

tornado.httpserver

• tornado.httpserver.HTTPRequest has moved to tornado.httpclient.HTTPServerRequest.
• HTTP implementation has been unified with tornado.simple_httpclient in tornado.http1connection.
• Now supports Transfer-Encoding: chunked for request bodies.
• Now supports Content-Encoding: gzip for request bodies if decompress_request=True is passed to the HTTPServer constructor.
• The connection attribute of HTTPServerRequest is now documented for public use; applications are expected to write their responses via the HTTPConnection interface.
• The HTTPServerRequest.write and HTTPServerRequest.finish methods are now deprecated. (RequestHandler.write and RequestHandler.finish are not deprecated; this only applies to the methods on HTTPServerRequest)
• HTTPServer now supports HTTPServerConnectionDelegate in addition to the old request_callback interface. The delegate interface supports streaming of request bodies.
• HTTPServer now detects the error of an application sending a Content-Length error that is inconsistent with the actual content.
• New constructor arguments max_header_size and max_body_size allow separate limits to be set for different parts of the request. max_body_size is applied even in streaming mode.
• New constructor argument chunk_size can be used to limit the amount of data read into memory at one time per request.
• New constructor arguments idle_connection_timeout and body_timeout allow time limits to be placed on the reading of requests.
• Form-encoded message bodies are now parsed for all HTTP methods, not just POST, PUT, and PATCH.
**tornado.httputil**

- `HTTPServerRequest` was moved to this module from `tornado.httpserver`.
- New base classes `HTTPConnection`, `HTTPServerConnectionDelegate`, and `HTTPMessageDelegate` define the interaction between applications and the HTTP implementation.

**tornado.ioloop**

- `IOLoop.add_handler` and related methods now accept file-like objects in addition to raw file descriptors. Passing the objects is recommended (when possible) to avoid a garbage-collection-related problem in unit tests.
- New method `IOLoop.clear_instance` makes it possible to uninstall the singleton instance.
- Timeout scheduling is now more robust against slow callbacks.
- `IOLoop.add_timeout` is now a bit more efficient.
- When a function run by the `IOLoop` returns a `Future` and that `Future` has an exception, the `IOLoop` will log the exception.
- New method `IOLoop.spawn_callback` simplifies the process of launching a fire-and-forget callback that is separated from the caller’s stack context.
- New methods `IOLoop.call_later` and `IOLoop.call_at` simplify the specification of relative or absolute timeouts (as opposed to `add_timeout`, which used the type of its argument).

**tornado.iostream**

- The callback argument to most `IOStream` methods is now optional. When called without a callback the method will return a `Future` for use with coroutines.
- New method `IOStream.start_tls` converts an `IOStream` to an `SSLIOStream`.
- No longer gets confused when an `IOError` or `OSError` without an `errno` attribute is raised.
- `BaseIOStream.read_bytes` now accepts a `partial` keyword argument, which can be used to return before the full amount has been read. This is a more coroutine-friendly alternative to `streaming_callback`.
- `BaseIOStream.read_until` and `read_until_regex` now accept a `max_bytes` keyword argument which will cause the request to fail if it cannot be satisfied from the given number of bytes.
- `IOStream` no longer reads from the socket into memory if it does not need data to satisfy a pending read. As a side effect, the close callback will not be run immediately if the other side closes the connection while there is unconsumed data in the buffer.
- The default `chunk_size` has been increased to 64KB (from 4KB)
- The `IOStream` constructor takes a new keyword argument `max_write_buffer_size` (defaults to unlimited). Calls to `BaseIOStream.write` will raise `StreamBufferFullError` if the amount of unsent buffered data exceeds this limit.
- `ETIMEDOUT` errors are no longer logged. If you need to distinguish timeouts from other forms of closed connections, examine `stream.error` from a close callback.
tornado.netutil

- When `bind_sockets` chooses a port automatically, it will now use the same port for IPv4 and IPv6.
- TLS compression is now disabled by default on Python 3.3 and higher (it is not possible to change this option in older versions).

**tornado.options**

- It is now possible to disable the default logging configuration by setting `options.logging` to `None` instead of the string "none".

**tornado.platform.asyncio**

- Now works on Python 2.6.
- Now works with Trollius version 0.3.

**tornado.platform.twisted**

- `TwistedIOLoop` now works on Python 3.3+ (with Twisted 14.0.0+).

**tornado.simple_httpclient**

- `simple_httpclient` has better support for IPv6, which is now enabled by default.
- Improved default cipher suite selection (Python 2.7+).
- HTTP implementation has been unified with `tornado.httpserver` in `tornado.http1connection`
- Streaming request bodies are now supported via the `body_producer` keyword argument to `tornado.httpclient.HTTPRequest`.
- The `expect_100_continue` keyword argument to `tornado.httpclient.HTTPRequest` allows the use of the HTTP Expect: 100-continue feature.
- `simple_httpclient` now raises the original exception (e.g. an `IOError`) in more cases, instead of converting everything to `HTTPError`.

**tornado.stack_context**

- The stack context system now has less performance overhead when no stack contexts are active.
**tornado.tcpclient**

- New module which creates TCP connections and IOStreams, including name resolution, connecting, and SSL handshakes.

**tornado.testing**

- `AsyncTestCase` now attempts to detect test methods that are generators but were not run with `@gen_test` or any similar decorator (this would previously result in the test silently being skipped).
- Better stack traces are now displayed when a test times out.
- The `@gen_test` decorator now passes along `*args, **kwargs` so it can be used on functions with arguments.
- Fixed the test suite when `unittest2` is installed on Python 3.

**tornado.web**

- It is now possible to support streaming request bodies with the `stream_request_body` decorator and the new `RequestHandler.data_received` method.
- `RequestHandler.flush` now returns a `Future` if no callback is given.
- New exception `Finish` may be raised to finish a request without triggering error handling.
- When gzip support is enabled, all `text/*` mime types will be compressed, not just those on a whitelist.
- `Application` now implements the `HTTPMessageDelegate` interface.
- HEAD requests in `StaticFileHandler` no longer read the entire file.
- `StaticFileHandler` now streams response bodies to the client.
- New setting `compress_response` replaces the existing `gzip` setting; both names are accepted.
- XSRF cookies that were not generated by this module (i.e. strings without any particular formatting) are once again accepted (as long as the cookie and body/header match). This pattern was common for testing and non-browser clients but was broken by the changes in Tornado 3.2.2.

**tornado.websocket**

- WebSocket connections from other origin sites are now rejected by default. Browsers do not use the same-origin policy for WebSocket connections as they do for most other browser-initiated communications. This can be surprising and a security risk, so we disallow these connections on the server side by default. To accept cross-origin websocket connections, override the new method `WebSocketHandler.check_origin`.
- `WebSocketHandler.close` and `WebSocketClientConnection.close` now support `code` and `reason` arguments to send a status code and message to the other side of the connection when closing. Both classes also have `close_code` and `close_reason` attributes to receive these values when the other side closes.
- The C speedup module now builds correctly with MSVC, and can support messages larger than 2GB on 64-bit systems.
- The fallback mechanism for detecting a missing C compiler now works correctly on Mac OS X.
- Arguments to `WebSocketHandler.open` are now decoded in the same way as arguments to `RequestHandler.get` and similar methods.
• It is now allowed to override `prepare` in a `WebSocketHandler`, and this method may generate HTTP responses (error pages) in the usual way. The HTTP response methods are still not allowed once the WebSocket handshake has completed.

tornado.wsgi

• New class `WSGIAdapter` supports running a Tornado `Application` on a WSGI server in a way that is more compatible with Tornado’s non-WSGI `HTTPServer`. `WSGIApplication` is deprecated in favor of using `WSGIAdapter` with a regular `Application`.

• `WSGIAdapter` now supports gzipped output.

6.9.31 What’s new in Tornado 3.2.2

June 3, 2014

Security fixes

• The XSRF token is now encoded with a random mask on each request. This makes it safe to include in compressed pages without being vulnerable to the BREACH attack. This applies to most applications that use both the `xsrf_cookies` and `gzip` options (or have gzip applied by a proxy).

Backwards-compatibility notes

• If Tornado 3.2.2 is run at the same time as older versions on the same domain, there is some potential for issues with the differing cookie versions. The `Application` setting `xsrf_cookie_version=1` can be used for a transitional period to generate the older cookie format on newer servers.

Other changes

• `tornado.platform.asyncio` is now compatible with `trollius` version 0.3.

6.9.32 What’s new in Tornado 3.2.1

May 5, 2014

Security fixes

• The signed-value format used by `RequestHandler.set_secure_cookie` and `RequestHandler.get_secure_cookie` has changed to be more secure. This is a disruptive change. The `secure_cookie` functions take new `version` parameters to support transitions between cookie formats.

• The new cookie format fixes a vulnerability that may be present in applications that use multiple cookies where the name of one cookie is a prefix of the name of another.

• To minimize disruption, cookies in the older format will be accepted by default until they expire. Applications that may be vulnerable can reject all cookies in the older format by passing `min_version=2` to `RequestHandler.get_secure_cookie`.

• Thanks to Joost Pol of Certified Secure for reporting this issue.
Backwards-compatibility notes

- Signed cookies issued by `RequestHandler.set_secure_cookie` in Tornado 3.2.1 cannot be read by older releases. If you need to run 3.2.1 in parallel with older releases, you can pass `version=1` to `RequestHandler.set_secure_cookie` to issue cookies that are backwards-compatible (but have a known weakness, so this option should only be used for a transitional period).

Other changes

- The C extension used to speed up the websocket module now compiles correctly on Windows with MSVC and 64-bit mode. The fallback to the pure-Python alternative now works correctly on Mac OS X machines with no C compiler installed.

6.9.33 What’s new in Tornado 3.2

Jan 14, 2014

Installation

- Tornado now depends on the `backports.ssl_match_hostname` when running on Python 2. This will be installed automatically when using `pip` or `easy_install`.
- Tornado now includes an optional C extension module, which greatly improves performance of websockets. This extension will be built automatically if a C compiler is found at install time.

New modules

- The `tornado.platform.asyncio` module provides integration with the `asyncio` module introduced in Python 3.4 (also available for Python 3.3 with `pip install asyncio`).

`tornado.auth`

- Added `GoogleOAuth2Mixin` support authentication to Google services with OAuth 2 instead of OpenID and OAuth 1.
- `FacebookGraphMixin` has been updated to use the current Facebook login URL, which saves a redirect.

`tornado.concurrent`

- `TracebackFuture` now accepts a `timeout` keyword argument (although it is still incorrect to use a non-zero timeout in non-blocking code).
tornado.curl_httpclient

- `tornado.curl_httpclient` now works on Python 3 with the soon-to-be-released pycurl 7.19.3, which will officially support Python 3 for the first time. Note that there are some unofficial Python 3 ports of pycurl (Ubuntu has included one for its past several releases); these are not supported for use with Tornado.

tornado.escape

- `xhtml_escape` now escapes apostrophes as well.
- `tornado.escape.utf8`, `to_unicode`, and `native_str` now raise `TypeError` instead of `AssertionError` when given an invalid value.

tornado.gen

- Coroutines may now yield dicts in addition to lists to wait for multiple tasks in parallel.
- Improved performance of `tornado.gen` when yielding a `Future` that is already done.

tornado.httpclient

- `tornado.httpclient.HTTPRequest` now uses property setters so that setting attributes after construction applies the same conversions as `__init__` (e.g. converting the body attribute to bytes).

tornado.httpserver

- Malformed x-www-form-urlencoded request bodies will now log a warning and continue instead of causing the request to fail (similar to the existing handling of malformed multipart/form-data bodies. This is done mainly because some libraries send this content type by default even when the data is not form-encoded.
- Fix some error messages for unix sockets (and other non-IP sockets)

tornado.ioloop

- `IOLoop` now uses `IOLoop.handle_callback_exception` consistently for error logging.
- `IOLoop` now frees callback objects earlier, reducing memory usage while idle.
- `IOLoop` will no longer call `logging.basicConfig` if there is a handler defined for the root logger or for the `tornado` or `tornado.application` loggers (previously it only looked at the root logger).
**tornado.iostream**

- **IOStream** now recognizes ECONNABORTED error codes in more places (which was mainly an issue on Windows).
- **IOStream** now frees memory earlier if a connection is closed while there is data in the write buffer.
- **PipeIOStream** now handles EAGAIN error codes correctly.
- **SSLIOStream** now initiates the SSL handshake automatically without waiting for the application to try and read or write to the connection.
- Swallow a spurious exception from set_nodelay when a connection has been reset.

**tornado.locale**

- **Locale.format_date** no longer forces the use of absolute dates in Russian.

**tornado.log**

- Fix an error from **tornado.log.enable_pretty_logging** when **sys.stderr** does not have an isatty method.
- **tornado.log.LogFormatter** now accepts keyword arguments `fmt` and `datefmt`.

**tornado.netutil**

- **is_valid_ip** (and therefore **HTTPRequest.remote_ip**) now rejects empty strings.
- Synchronously using **ThreadedResolver** at import time to resolve a unicode hostname no longer deadlocks.

**tornado.platform.twisted**

- **TwistedResolver** now has better error handling.

**tornado.process**

- **Subprocess** no longer leaks file descriptors if **subprocess.Popen** fails.

**tornado.simple_httpclient**

- **simple_httpclient** now applies the `connect_timeout` to requests that are queued and have not yet started.
- On Python 2.6, **simple_httpclient** now uses TLSv1 instead of SSLv3.
- **simple_httpclient** now enforces the connect timeout during DNS resolution.
- The embedded ca-certificates.crt file has been updated with the current Mozilla CA list.
tornado.web

- **StaticFileHandler** no longer fails if the client requests a **Range** that is larger than the entire file (Facebook has a crawler that does this).
- **RequestHandler.on_connection_close** now works correctly on subsequent requests of a keep-alive connection.
- New application setting **default_handler_class** can be used to easily set up custom 404 pages.
- New application settings **autoreload**, **compiled_template_cache**, **static_hash_cache**, and **serve_traceback** can be used to control individual aspects of debug mode.
- New methods **RequestHandler.get_query_argument** and **RequestHandler.get_body_argument** and new attributes **HTTPRequest.query_arguments** and **HTTPRequest.body_arguments** allow access to arguments without intermingling those from the query string with those from the request body.
- **RequestHandler.decode_argument** and related methods now raise an **HTTPError(400)** instead of **UnicodeDecodeError** when the argument could not be decoded.
- **RequestHandler.clear_all_cookies** now accepts **domain** and **path** arguments, just like **clear_cookie**.
- It is now possible to specify handlers by name when using the **tornado.web.URLSpec** class.
- **Application** now accepts 4-tuples to specify the **name** parameter (which previously required constructing a **tornado.web.URLSpec** object instead of a tuple).
- Fixed an incorrect error message when handler methods return a value other than None or a Future.
- Exceptions will no longer be logged twice when using both @asynchronous and @gen.coroutine

**tornado.websocket**

- **WebSocketHandler.write_message** now raises **WebSocketClosedError** instead of **AttributeError** when the connection has been closed.
- **websocket_connect** now accepts preconstructed **HTTPRequest** objects.
- Fix a bug with **WebSocketHandler** when used with some proxies that unconditionally modify the **Connection** header.
- **websocket_connect** now returns an error immediately for refused connections instead of waiting for the timeout.
- **WebSocketClientConnection** now has a **close** method.

**tornado.wsgi**

- **WSGICContainer** now calls the iterable’s **close()** method even if an error is raised, in compliance with the spec.
6.9.34 What’s new in Tornado 3.1.1

Sep 1, 2013

- StaticFileHandler no longer fails if the client requests a Range that is larger than the entire file (Facebook has a crawler that does this).
- RequestHandler.on_connection_close now works correctly on subsequent requests of a keep-alive connection.

6.9.35 What’s new in Tornado 3.1

Jun 15, 2013

Multiple modules

- Many reference cycles have been broken up throughout the package, allowing for more efficient garbage collection on CPython.
- Silenced some log messages when connections are opened and immediately closed (i.e. port scans), or other situations related to closed connections.
- Various small speedups: HttpHeaders case normalization, UIModule proxy objects, precompile some regexes.

**tornado.auth**

- OAuthMixin always sends oauth_version=1.0 in its request as required by the spec.
- FacebookGraphMixin now uses self._FACEBOOK_BASE_URL in facebook_request to allow the base url to be overridden.
- The authenticate_redirect and authorize_redirect methods in the tornado.auth mixin classes all now return Futures. These methods are asynchronous in OAuthMixin and derived classes, although they do not take a callback. The Future these methods return must be yielded if they are called from a function decorated with gen.coroutine (but not gen.engine).
- TwitterMixin now uses /account/verify_credentials to get information about the logged-in user, which is more robust against changing screen names.
- The demos directory (in the source distribution) has a new twitter demo using TwitterMixin.

**tornado.escape**

- url_escape and url_unescape have a new plus argument (defaulting to True for consistency with the previous behavior) which specifies whether they work like urllib.parse.unquote or urllib.parse.unquote_plus.
tornado.gen

- Fixed a potential memory leak with long chains of `tornado.gen` coroutines.

tornado.httpclient

- `tornado.httpclient.HTTPRequest` takes a new argument `auth_mode`, which can be either `basic` or `digest`. Digest authentication is only supported with `tornado.curl_httpclient`.
- `tornado.curl_httpclient` no longer goes into an infinite loop when `pycurl` returns a negative timeout.
- `curl_httpclient` now supports the `PATCH` and `OPTIONS` methods without the use of `allow_nonstandard_methods=True`.
- Worked around a class of bugs in `libcurl` that would result in errors from `IOLoop.update_handler` in various scenarios including digest authentication and socks proxies.
- The `TCP_NODELAY` flag is now set when appropriate in `simple_httpclient`.
- `simple_httpclient` no longer logs exceptions, since those exceptions are made available to the caller as `HTTPResponse.error`.

tornado.httpserver

- `tornado.httpserver.HTTPServer` handles malformed HTTP headers more gracefully.
- `HTTPServer` now supports lists of IPs in `X-Forwarded-For` (it chooses the last, i.e. nearest one).
- Memory is now reclaimed promptly on CPython when an HTTP request fails because it exceeded the maximum upload size.
- The `TCP_NODELAY` flag is now set when appropriate in `HTTPServer`.
- The `HTTPServer no_keep_alive` option is now respected with HTTP 1.0 connections that explicitly pass `Connection: keep-alive`.
- The `str` and `repr` of `tornado.httpserver.HTTPRequest` no longer include the request body, reducing log spam on errors (and potential exposure/retention of private data).

tornado.httputil

- The cache used in `HTTPHeaders` will no longer grow without bound.

tornado.ioloop

- Some `IOLoop` implementations (such as `pyzmq`) accept objects other than integer file descriptors; these objects will now have their `.close()` method called when the `IOLoop` is closed with `all_fds=True`.
- The stub handles left behind by `IOLoop.remove_timeout` will now get cleaned up instead of waiting to expire.
tornado.iostream

- Fixed a bug in `BaseIOStream.read_until_close` that would sometimes cause data to be passed to the final callback instead of the streaming callback.
- The `IOStream` close callback is now run more reliably if there is an exception in `_try_inline_read`.
- New method `BaseIOStream.set_nodelay` can be used to set the `TCP_NODELAY` flag.
- Fixed a case where errors in `SSLIOStream.connect` (and `SimpleAsyncHTTPClient`) were not being reported correctly.

**tornado.locale**

- `Locale.format_date` now works on Python 3.

**tornado.netutil**

- The default `Resolver` implementation now works on Solaris.
- `Resolver` now has a `close` method.
- Fixed a potential CPU DoS when `tornado.netutil.ssl_match_hostname` is used on certificates with an abusive wildcard pattern.
- All instances of `ThreadedResolver` now share a single thread pool, whose size is set by the first one to be created (or the static `Resolver.configure` method).
- `ExecutorResolver` is now documented for public use.
- `bind_sockets` now works in configurations with incomplete IPv6 support.

**tornado.options**

- `tornado.options.define` with `multiple=True` now works on Python 3.
- `tornado.options.options` and other `OptionParser` instances support some new dict-like methods: `items()`, iteration over keys, and (read-only) access to options with square braket syntax. `OptionParser.group_dict` returns all options with a given group name, and `OptionParser.as_dict` returns all options.

**tornado.process**

- `tornado.process.Subprocess` no longer leaks file descriptors into the child process, which fixes a problem in which the child could not detect that the parent process had closed its stdin pipe.
- `Subprocess.set_exit_callback` now works for subprocesses created without an explicit `io_loop` parameter.
tornado.stack_context

- `tornado.stack_context` has been rewritten and is now much faster.
- New function `run_with_stack_context` facilitates the use of stack contexts with coroutines.

tornado.tcpserver

- The constructors of `TCPServer` and `HTTPServer` now take a `max_buffer_size` keyword argument.

tornado.template

- Some internal names used by the template system have been changed; now all “reserved” names in templates start with `_tt_`.

tornado.testing

- `tornado.testing.AsyncTestCase.wait` now raises the correct exception when it has been modified by `tornado.stack_context`.
- `tornado.testing.gen_test` can now be called as `@gen_test(timeout=60)` to give some tests a longer timeout than others.
- The environment variable `ASYNC_TEST_TIMEOUT` can now be set to override the default timeout for `AsyncTestCase.wait` and `gen_test`.
- `bind_unused_port` now passes `None` instead of `0` as the port to `getaddrinfo`, which works better with some unusual network configurations.

tornado.util

- `tornado.util.import_object` now works with top-level module names that do not contain a dot.
- `tornado.util.import_object` now consistently raises `ImportError` instead of `AttributeError` when it fails.

tornado.web

- The `handlers` list passed to the `tornado.web.Application` constructor and `add_handlers` methods can now contain lists in addition to tuples and `URLSpec` objects.
- `tornado.web.StaticFileHandler` now works on Windows when the client passes an `If-Modified-Since` timestamp before 1970.
- New method `RequestHandler.log_exception` can be overridden to customize the logging behavior when an exception is uncaught. Most apps that currently override `_handle_request_exception` can now use a combination of `RequestHandler.log_exception` and `write_error`.
- `RequestHandler.get_argument` now raises `MissingArgumentError` (a subclass of `tornado.web.HTTPError`, which is what it raised previously) if the argument cannot be found.
- `Application.reverse_url` now uses `url_escape` with `plus=False`, i.e. spaces are encoded as `%20` instead of `+`. 
- Arguments extracted from the url path are now decoded with `url_unescape` with `plus=False`, so plus signs are left as-is instead of being turned into spaces.

- `RequestHandler.send_error` will now only be called once per request, even if multiple exceptions are caught by the stack context.

- The `tornado.web.asynchronous` decorator is no longer necessary for methods that return a `Future` (i.e. those that use the `gen.coroutine` or `return_future` decorators)

- `RequestHandler.prepare` may now be asynchronous if it returns a `Future`. The `tornado.web.asynchronous` decorator is not used with `prepare`; one of the `Future`-related decorators should be used instead.

- `RequestHandler.current_user` may now be assigned to normally.

- `RequestHandler.redirect` no longer silently strips control characters and whitespace. It is now an error to pass control characters, newlines or tabs.

- `StaticFileHandler` has been reorganized internally and now has additional extension points that can be overridden in subclasses.

- `StaticFileHandler` now supports HTTP Range requests. `StaticFileHandler` is still not suitable for files too large to comfortably fit in memory, but Range support is necessary in some browsers to enable seeking of HTML5 audio and video.

- `StaticFileHandler` now uses longer hashes by default, and uses the same hashes for `Etag` as it does for versioned urls.

- `StaticFileHandler.make_static_url` and `RequestHandler.static_url` now have an additional keyword argument `include_version` to suppress the url versioning.

- `StaticFileHandler` now reads its file in chunks, which will reduce memory fragmentation.

- Fixed a problem with the `Date` header and cookie expiration dates when the system locale is set to a non-english configuration.

**tornado.websocket**

- `WebSocketHandler` now catches `StreamClosedError` and runs `on_close` immediately instead of logging a stack trace.

- New method `WebSocketHandler.set_nodelay` can be used to set the TCP_NODELAY flag.

**tornado.wsgi**

- Fixed an exception in `WSGIContainer` when the connection is closed while output is being written.

### 6.9.36 What's new in Tornado 3.0.2

#### Jun 2, 2013

- `tornado.auth.TwitterMixin` now defaults to version 1.1 of the Twitter API, instead of version 1.0 which is being discontinued on June 11. It also now uses HTTPS when talking to Twitter.

- Fixed a potential memory leak with a long chain of `gen.coroutine` or `gen.engine` functions.
6.9.37 What’s new in Tornado 3.0.1

Apr 8, 2013

• The interface of `tornado.auth.FacebookGraphMixin` is now consistent with its documentation and the rest of the module. The `get_authenticated_user` and `facebook_request` methods return a `Future` and the callback argument is optional.

• The `tornado.testing.gen_test` decorator will no longer be recognized as a (broken) test by `nose`.

• Work around a bug in Ubuntu 13.04 betas involving an incomplete backport of the `ssl.match_hostname` function.

• `tornado.websocket.websocket_connect` now fails cleanly when it attempts to connect to a non-websocket url.

• `tornado.testing.LogTrapTestCase` once again works with byte strings on Python 2.

• The `request` attribute of `tornado.httpclient.HTTPResponse` is now always an `HTTPRequest`, never a `_RequestProxy`.

• Exceptions raised by the `tornado.gen` module now have better messages when tuples are used as callback keys.

6.9.38 What’s new in Tornado 3.0

Mar 29, 2013

Highlights

• The callback argument to many asynchronous methods is now optional, and these methods return a `Future`. The `tornado.gen` module now understands Futures, and these methods can be used directly without a `gen` Task wrapper.

• New function `IOLoop.current` returns the `IOLoop` that is running on the current thread (as opposed to `IOLoop.instance`, which returns a specific thread’s (usually the main thread’s) IOLoop.

• New class `tornado.netutil.Resolver` provides an asynchronous interface to DNS resolution. The default implementation is still blocking, but non-blocking implementations are available using one of three optional dependencies: `ThreadedResolver` using the `concurrent.futures` thread pool, `tornado.platform.caresresolver.CaresResolver` using the `pycares` library, or `tornado.platform.twisted.TwistedResolver` using `twisted`.

• Tornado’s logging is now less noisy, and it no longer goes directly to the root logger, allowing for finer-grained configuration.

• New class `tornado.process.Subprocess` wraps `subprocess.Popen` with `PipeIOStream` access to the child’s file descriptors.

• `IOLoop` now has a static `configure` method like the one on `AsyncHTTPClient`, which can be used to select an `IOLoop` implementation other than the default.

• `IOLoop` can now optionally use a monotonic clock if available (see below for more details).
Backwards-incompatible changes

- Python 2.5 is no longer supported. Python 3 is now supported in a single codebase instead of using 2to3
- The tornado.database module has been removed. It is now available as a separate package, torndb
- Functions that take an io_loop parameter now default to IOLoop.current() instead of IOLoop.instance().
- Empty HTTP request arguments are no longer ignored. This applies to HTTPRequest.arguments and RequestHandler.get_argument[s] in WSGI and non-WSGI modes.
- On Python 3, tornado.escape.json_encode no longer accepts byte strings.
- On Python 3, the get_authenticated_user methods in tornado.auth now return character strings instead of byte strings.
- tornado.netutil.TCPServer has moved to its own module, tornado.tcpserver.
- The Tornado test suite now requires unittest2 when run on Python 2.6.
- tornado.options.options is no longer a subclass of dict; attribute-style access is now required.

Detailed changes by module

Multiple modules

- Tornado no longer logs to the root logger. Details on the new logging scheme can be found under the tornado.log module. Note that in some cases this will require that you add an explicit logging configuration in order to see any output (perhaps just calling logging.basicConfig()), although both IOLoop.start() and tornado.options.parse_command_line will do this for you.
- On python 3.2+, methods that take an ssl_options argument (on SSLIOStream, TCPServer, and HTTPServer) now accept either a dictionary of options or an ssl.SSLContext object.
- New optional dependency on concurrent.futures to provide better support for working with threads. concurrent.futures is in the standard library for Python 3.2+, and can be installed on older versions with pip install futures.

tornado.autoreload

- tornado.autoreload is now more reliable when there are errors at import time.
- Calling tornado.autoreload.start (or creating an Application with debug=True) twice on the same IOLoop now does nothing (instead of creating multiple periodic callbacks). Starting autoreload on more than one IOLoop in the same process now logs a warning.
- Scripts run by autoreload no longer inherit __future__ imports used by Tornado.
tornado.auth

- On Python 3, the `get_authenticated_user` method family now returns character strings instead of byte strings.
- Asynchronous methods defined in `tornado.auth` now return a `Future`, and their callback argument is optional. The `Future` interface is preferred as it offers better error handling (the previous interface just logged a warning and returned None).
- The `tornado.auth` mixin classes now define a method `get_auth_http_client`, which can be overridden to use a non-default `AsyncHTTPClient` instance (e.g. to use a different `IOLoop`).
- Subclasses of `OAuthMixin` are encouraged to override `OAuthMixin._oauth_get_user_future` instead of `_oauth_get_user`, although both methods are still supported.

tornado.concurrent

- New module `tornado.concurrent` contains code to support working with `concurrent.futures`, or to emulate future-based interface when that module is not available.

tornado.curl_httpclient

- Preliminary support for `tornado.curl_httpclient` on Python 3. The latest official release of pycurl only supports Python 2, but Ubuntu has a port available in 12.10 (`apt-get install python3-pycurl`). This port currently has bugs that prevent it from handling arbitrary binary data but it should work for textual (utf8) resources.
- Fix a crash with libcurl 7.29.0 if a curl object is created and closed without being used.

tornado.escape

- On Python 3, `json_encode` no longer accepts byte strings. This mirrors the behavior of the underlying json module. Python 2 behavior is unchanged but should be faster.

tornado.gen

- New decorator `@gen.coroutine` is available as an alternative to `@gen.engine`. It automatically returns a `Future`, and within the function instead of calling a callback you return a value with `raise gen.Return(value)` (or simply `return value` in Python 3.3).
- Generators may now yield `Future` objects.
- Callbacks produced by `gen.Callback` and `gen.Task` are now automatically stack-context-wrapped, to minimize the risk of context leaks when used with asynchronous functions that don’t do their own wrapping.
- Fixed a memory leak involving generators, `RequestHandler.flush`, and clients closing connections while output is being written.
- Yielding a large list no longer has quadratic performance.
tornado.httpclient

- `AsyncHTTPClient.fetch` now returns a `Future` and its callback argument is optional. When the future interface is used, any error will be raised automatically, as if `HTTPResponse.rethrow` was called.
- `AsyncHTTPClient.configure` and all `AsyncHTTPClient` constructors now take a `defaults` keyword argument. This argument should be a dictionary, and its values will be used in place of corresponding attributes of `HTTPRequest` that are not set.
- All unset attributes of `tornado.httpclient.HTTPRequest` are now `None`. The default values of some attributes (`connect_timeout`, `request_timeout`, `follow_redirects`, `max_redirects`, `use_gzip`, `proxy_password`, `allow_nonstandard_methods`, and `validate_cert`) have been moved from `HTTPRequest` to the client implementations.
- The `max_clients` argument to `AsyncHTTPClient` is now a keyword-only argument.
- Keyword arguments to `AsyncHTTPClient.configure` are no longer used when instantiating an implementation subclass directly.
- Secondary `AsyncHTTPClient` callbacks (streaming_callback, header_callback, and prepare_curl_callback) now respect StackContext.

tornado.httpserver

- `HTTPServer` no longer logs an error when it is unable to read a second request from an HTTP 1.1 keep-alive connection.
- `HTTPServer` now takes a `protocol` keyword argument which can be set to `https` if the server is behind an SSL-decoding proxy that does not set any supported X-headers.
- `tornado.httpserver.HTTPConnection` now has a `set_close_callback` method that should be used instead of reaching into its `stream` attribute.
- Empty HTTP request arguments are no longer ignored. This applies to `HTTPRequest.arguments` and `RequestHandler.get_argument[s]` in WSGI and non-WSGI modes.

tornado.ioloop

- New function `IOLoop.current` returns the `IOLoop` that is running on the current thread (as opposed to `IOLoop.instance`, which returns a specific thread’s (usually the main thread’s) `IOLoop`).
- New method `IOLoop.add_future` to run a callback on the IOLoop when an asynchronous `Future` finishes.
- `IOLoop` now has a static `configure` method like the one on `AsyncHTTPClient`, which can be used to select an `IOLoop` implementation other than the default.
- The `IOLoop` poller implementations (select, epoll, kqueue) are now available as distinct subclasses of `IOLoop`. Instantiating `IOLoop` will continue to automatically choose the best available implementation.
- The `IOLoop` constructor has a new keyword argument `time_func`, which can be used to set the time function used when scheduling callbacks. This is most useful with the `time.monotonic` function, introduced in Python 3.3 and backported to older versions via the `monotime` module. Using a monotonic clock here avoids problems when the system clock is changed.
- New function `IOLoop.time` returns the current time according to the IOLoop. To use the new monotonic clock functionality, all calls to `IOLoop.add_timeout` must be either pass a `datetime.timedelta` or a time relative to `IOLoop.time`, not `time.time`. (`time.time` will continue to work only as long as the IOLoop’s `time_func` argument is not used).
• New convenience method `IOLoop.run_sync` can be used to start an IOLoop just long enough to run a single coroutine.

• New method `IOLoop.add_callback_from_signal` is safe to use in a signal handler (the regular `add_callback` method may deadlock).

• `IOLoop` now uses `signal.set_wakeup_fd` where available (Python 2.6+ on Unix) to avoid a race condition that could result in Python signal handlers being delayed.

• Method `IOLoop.running()` has been removed.

• `IOLoop` has been refactored to better support subclassing.

• `IOLoop.add_callback` and `add_callback_from_signal` now take `*args, **kwargs` to pass along to the callback.

`tornado.iostream`

• `IOStream.connect` now has an optional `server_hostname` argument which will be used for SSL certificate validation when applicable. Additionally, when supported (on Python 3.2+), this hostname will be sent via SNI (and this is supported by `tornado.simple_httpclient`)

• Much of `IOStream` has been refactored into a separate class `BaseIOStream`.

• New class `tornado.iostream.PipeIOStream` provides the IOStream interface on pipe file descriptors.

• `IOStream` now raises a new exception `tornado.iostream.StreamClosedError` when you attempt to read or write after the stream has been closed (by either side).

• `IOStream` now simply closes the connection when it gets an ECONNRESET error, rather than logging it as an error.

• `BaseIOStream.error` no longer picks up unrelated exceptions.

• `BaseIOStream.close` now has an `exc_info` argument (similar to the one used in the `logging` module) that can be used to set the stream’s `error` attribute when closing it.

• `BaseIOStream.read_until_close` now works correctly when it is called while there is buffered data.

• Fixed a major performance regression when run on PyPy (introduced in Tornado 2.3).

`tornado.log`

• New module containing `enable_pretty_logging` and `LogFormatter`, moved from the options module.

• `LogFormatter` now handles non-ascii data in messages and tracebacks better.

`tornado.netutil`

• New class `tornado.netutil.Resolver` provides an asynchronous interface to DNS resolution. The default implementation is still blocking, but non-blocking implementations are available using one of three optional dependencies: `ThreadedResolver` using the `concurrent.futures` thread pool, `tornado.platform.caresresolver.CaresResolver` using the `pycares` library, or `tornado.platform.twisted.TwistedResolver` using `twisted`

• New function `tornado.netutil.is_valid_ip` returns true if a given string is a valid IP (v4 or v6) address.

• `tornado.netutil.bind_sockets` has a new `flags` argument that can be used to pass additional flags to `getaddrinfo`. 

226 Chapter 6. Documentation
• **tornado.netutil.bind_sockets** no longer sets AI_ADDRCONFIG; this will cause it to bind to both ipv4 and ipv6 more often than before.

• **tornado.netutil.bind_sockets** now works when Python was compiled with --disable-ipv6 but IPv6 DNS resolution is available on the system.

• **tornado.netutil.TCPServer** has moved to its own module, **tornado.tcpserver**.

**tornado.options**

• The class underlying the functions in **tornado.options** is now public (**tornado.options.OptionParser**). This can be used to create multiple independent option sets, such as for subcommands.

• **tornado.options.parse_config_file** now configures logging automatically by default, in the same way that **parse_command_line** does.

• New function **tornado.options.add_parse_callback** schedules a callback to be run after the command line or config file has been parsed. The keyword argument final=False can be used on either parsing function to suppress these callbacks.

• **tornado.options.define** now takes a callback argument. This callback will be run with the new value whenever the option is changed. This is especially useful for options that set other options, such as by reading from a config file.

• **tornado.options.parse_command_line** --help output now goes to stderr rather than stdout.

• **tornado.options.options** is no longer a subclass of dict; attribute-style access is now required.

• **tornado.options.options** (and **OptionParser** instances generally) now have a mockable() method that returns a wrapper object compatible with mock.patch.

• Function **tornado.options.enable_pretty_logging** has been moved to the **tornado.log** module.

**tornado.platform.caresresolver**

• New module containing an asynchronous implementation of the Resolver interface, using the pycares library.

**tornado.platform.twisted**

• New class **tornado.platform.twisted.TwistedIOLoop** allows Tornado code to be run on the Twisted reactor (as opposed to the existing TornadoReactor, which bridges the gap in the other direction).

• New class **tornado.platform.twisted.TwistedResolver** is an asynchronous implementation of the Resolver interface.

**tornado.process**

• New class **tornado.process.Subprocess** wraps subprocess.Popen with PipeIOLStream access to the child’s file descriptors.
**tornado.simple_httpclient**

- **SimpleAsyncHTTPClient** now takes a `resolver` keyword argument (which may be passed to either the constructor or `configure`), to allow it to use the new non-blocking `tornado.netutil.Resolver`.
- When following redirects, `SimpleAsyncHTTPClient` now treats a 302 response code the same as a 303. This is contrary to the HTTP spec but consistent with all browsers and other major HTTP clients (including CurlAsyncHTTPClient).
- The behavior of `header_callback` with `SimpleAsyncHTTPClient` has changed and is now the same as that of CurlAsyncHTTPClient. The header callback now receives the first line of the response (e.g. `HTTP/1.0 200 OK`) and the final empty line.
- `tornado.simple_httpclient` now accepts responses with a 304 status code that include a `Content-Length` header.
- Fixed a bug in which `SimpleAsyncHTTPClient` callbacks were being run in the client's `stack_context`.

**tornado.stack_context**

- `stack_context.wrap` now runs the wrapped callback in a more consistent environment by recreating contexts even if they already exist on the stack.
- Fixed a bug in which stack contexts could leak from one callback chain to another.
- Yield statements inside a `with` statement can cause stack contexts to become inconsistent; an exception will now be raised when this case is detected.

**tornado.template**

- Errors while rendering templates no longer log the generated code, since the enhanced stack traces (from version 2.1) should make this unnecessary.
- The `{% apply %}` directive now works properly with functions that return both unicode strings and byte strings (previously only byte strings were supported).
- Code in templates is no longer affected by Tornado's `__future__` imports (which previously included `absolute_import` and `division`).

**tornado.testing**

- New function `tornado.testing.bind_unused_port` both chooses a port and binds a socket to it, so there is no risk of another process using the same port. `get_unused_port` is now deprecated.
- New decorator `tornado.testing.gen_test` can be used to allow for yielding `tornado.gen` objects in tests, as an alternative to the `stop` and `wait` methods of `AsyncTestCase`.
- `tornado.testing.AsyncTestCase` and friends now extend `unittest2.TestCase` when it is available (and continue to use the standard `unittest` module when `unittest2` is not available)
- `tornado.testing.ExpectLog` can be used as a finer-grained alternative to `tornado.testing.LogTrapTestCase`.
- The command-line interface to `tornado.testing.main` now supports additional arguments from the underlying `unittest` module: `verbose`, `quiet`, `failfast`, `catch`, `buffer`. 

---

228 Chapter 6. Documentation
The deprecated \texttt{--autoreload} option of \texttt{tornado.testing.main} has been removed. Use \texttt{python -m tornado.autoreload} as a prefix command instead.

The \texttt{--httpclient} option of \texttt{tornado.testing.main} has been moved to \texttt{tornado.test.runtests} so as not to pollute the application option namespace. The \texttt{tornado.options} module's new callback support now makes it easy to add options from a wrapper script instead of putting all possible options in \texttt{tornado.testing.main}.

\texttt{AsyncHTTPTestCase} no longer calls \texttt{AsyncHTTPClient.close} for tests that use the singleton \texttt{IOLoop.instance}.

\texttt{LogTrapTestCase} no longer fails when run in unknown logging configurations. This allows tests to be run under \texttt{nose}, which does its own log buffering (\texttt{LogTrapTestCase} doesn’t do anything useful in this case, but at least it doesn’t break things any more).

\texttt{tornado.util}

\texttt{tornado.util.b} (which was only intended for internal use) is gone.

\texttt{tornado.web}

\texttt{RequestHandler.set_header} now overwrites previous header values case-insensitively.

\texttt{tornado.web.RequestHandler} has new attributes \texttt{path_args} and \texttt{path_kwargs}, which contain the positional and keyword arguments that are passed to the \texttt{get/post/etc} method. These attributes are set before those methods are called, so they are available during \texttt{prepare()}

\texttt{tornado.web.ErrorHandler} no longer requires XSRF tokens on POST requests, so posts to an unknown url will always return 404 instead of complaining about XSRF tokens.

Several methods related to HTTP status codes now take a \texttt{reason} keyword argument to specify an alternate “reason” string (i.e. the “Not Found” in “HTTP/1.1 404 Not Found”). It is now possible to set status codes other than those defined in the spec, as long as a reason string is given.

The Date HTTP header is now set by default on all responses.

\texttt{Etag/If-None-Match} requests now work with \texttt{StaticFileHandler}.

\texttt{StaticFileHandler} no longer sets \texttt{Cache-Control: public} unnecessarily.

When gzip is enabled in a \texttt{tornado.web.Application}, appropriate \texttt{Vary: Accept-Encoding} headers are now sent.

It is no longer necessary to pass all handlers for a host in a single \texttt{Application.add_handlers} call. Now the request will be matched against the handlers for any \texttt{host_pattern} that includes the request’s \texttt{Host} header.

\texttt{tornado.websocket}

Client-side WebSocket support is now available: \texttt{tornado.websocket.websocket_connect}

\texttt{WebSocketHandler} has new methods \texttt{ping} and \texttt{on_pong} to send pings to the browser (not supported on the draft76 protocol)
6.9.39 What’s new in Tornado 2.4.1

Nov 24, 2012

Bug fixes

- Fixed a memory leak in `tornado.stack_context` that was especially likely with long-running `@gen.engine` functions.
- `tornado.auth.TwitterMixin` now works on Python 3.
- Fixed a bug in which `IOStream.read_until_close` with a streaming callback would sometimes pass the last chunk of data to the final callback instead of the streaming callback.

6.9.40 What’s new in Tornado 2.4

Sep 4, 2012

General

- Fixed Python 3 bugs in `tornado.auth`, `tornado.locale`, and `tornado.wsgi`.

HTTP clients

- Removed `max_simultaneous_connections` argument from `tornado.httpclient` (both implementations). This argument hasn’t been useful for some time (if you were using it you probably want `max_clients` instead)
- `tornado.simple_httpclient` now accepts and ignores HTTP 1xx status responses.

`tornado.ioloop` and `tornado.iostream`

- Fixed a bug introduced in 2.3 that would cause `IOLstream` close callbacks to not run if there were pending reads.
- Improved error handling in `SSLIOStream` and SSL-enabled `TCPServer`.
- `SSLIOStream.get_ssl_certificate` now has a `binary_form` argument which is passed to `SSLSocket.getpeercaert`.
- `SSLIOStream.write` can now be called while the connection is in progress, same as non-SSL `IOLstream` (but be careful not to send sensitive data until the connection has completed and the certificate has been verified).
- `IOLoop.add_handler` cannot be called more than once with the same file descriptor. This was always true for `epoll`, but now the other implementations enforce it too.
- On Windows, `TCPServer` uses `SO_EXCLUSIVEADDRUSER` instead of `SO_REUSEADDR`. 
tornado.template

- {% break %} and {% continue %} can now be used looping constructs in templates.
- It is no longer an error for an if/else/for/etc block in a template to have an empty body.

tornado.testing

- New class tornado.testing.AsyncHTTPSTestCase is like AsyncHTTPTestcase, but enables SSL for the testing server (by default using a self-signed testing certificate).
- tornado.testing.main now accepts additional keyword arguments and forwards them to unittest.main.

tornado.web

- New method RequestHandler.get_template_namespace can be overridden to add additional variables without modifying keyword arguments to render_string.
- RequestHandler.add_header now works with WSGIApplication.
- RequestHandler.get_secure_cookie now handles a potential error case.
- RequestHandler.__init__ now calls super().__init__ to ensure that all constructors are called when multiple inheritance is used.
- Docs have been updated with a description of all available Application settings

Other modules

- OAuthMixin now accepts "oob" as a callback_uri.
- OpenIdMixin now also returns the claimed_id field for the user.
- tornado.platform.twisted shutdown sequence is now more compatible.
- The logging configuration used in tornado.options is now more tolerant of non-ascii byte strings.

6.9.41 What’s new in Tornado 2.3

May 31, 2012

HTTP clients

- tornado.httpclient.HTTPClient now supports the same constructor keyword arguments as AsyncHTTPClient.
- The max_clients keyword argument to AsyncHTTPClient.configure now works.
- tornado.simple_httpclient now supports the OPTIONS and PATCH HTTP methods.
- tornado.simple_httpclient is better about closing its sockets instead of leaving them for garbage collection.
- tornado.simple_httpclient correctly verifies SSL certificates for URLs containing IPv6 literals (This bug affected Python 2.5 and 2.6).
• tornado.simple_httpclient no longer includes basic auth credentials in the Host header when those credentials are extracted from the URL.

• tornado.simple_httpclient no longer modifies the caller-supplied header dictionary, which caused problems when following redirects.

• tornado.curl_httpclient now supports client SSL certificates (using the same client_cert and client_key arguments as tornado.simple_httpclient)

HTTP Server

• HTTPServer now works correctly with paths starting with //

• HTTPHeaders.copy (inherited from dict.copy) now works correctly.

• HTTPConnection.address is now always the socket address, even for non-IP sockets. HTTPRequest.remote_ip is still always an IP-style address (fake data is used for non-IP sockets)

• Extra data at the end of multipart form bodies is now ignored, which fixes a compatibility problem with an iOS HTTP client library.

IOLoop and IOStream

• IOStream now has an error attribute that can be used to determine why a socket was closed.

• tornado.iostream.IOStream.read_until and read_until_regex are much faster with large input.

• IOStream.write performs better when given very large strings.

• IOLoop.instance() is now thread-safe.

tornado.options

• tornado.options options with multiple=True that are set more than once now overwrite rather than append. This makes it possible to override values set in parse_config_file with parse_command_line.

• tornado.options --help output is now prettier.

• tornado.options.options now supports attribute assignment.

tornado.template

• Template files containing non-ASCII (utf8) characters now work on Python 3 regardless of the locale environment variables.

• Templates now support else clauses in try/except/finally/else blocks.
tornado.web

- `tornado.web.RequestHandler` now supports the PATCH HTTP method. Note that this means any existing methods named `patch` in `RequestHandler` subclasses will need to be renamed.
- `tornado.web.addslash` and `removeslash` decorators now send permanent redirects (301) instead of temporary (302).
- `RequestHandler.flush` now invokes its callback whether there was any data to flush or not.
- Repeated calls to `RequestHandler.set_cookie` with the same name now overwrite the previous cookie instead of producing additional copies.
- `tornado.web.OutputTransform.transform_first_chunk` now takes and returns a status code in addition to the headers and chunk. This is a backwards-incompatible change to an interface that was never technically private, but was not included in the documentation and does not appear to have been used outside Tornado itself.
- Fixed a bug on python versions before 2.6.5 when `tornado.web.URLSpec` regexes are constructed from unicode strings and keyword arguments are extracted.
- The `reverse_url` function in the template namespace now comes from the `RequestHandler` rather than the `Application`. (Unless overridden, `RequestHandler.reverse_url` is just an alias for the `Application` method).
- The `Etag` header is now returned on 304 responses to an `If-None-Match` request, improving compatibility with some caches.
- `tornado.web` will no longer produce responses with status code 304 that also have entity headers such as `Content-Length`.

Other modules

- `tornado.auth.FacebookGraphMixin` no longer sends `post_args` redundantly in the url.
- The `extra_params` argument to `tornado.escape.linkify` may now be a callable, to allow parameters to be chosen separately for each link.
- `tornado.gen` no longer leaks `StackContexts` when a `@gen.engine` wrapped function is called repeatedly.
- `tornado.locale.get_supported_locales` no longer takes a meaningless `cls` argument.
- `StackContext` instances now have a deactivation callback that can be used to prevent further propagation.
- `tornado.testing.AsyncTestCase.wait` now resets its timeout on each call.
- `tornado.wsgi.WSGIApplication` now parses arguments correctly on Python 3.
- Exception handling on Python 3 has been improved; previously some exceptions such as `UnicodeDecodeError` would generate `TypeErrors`
6.9.42 What’s new in Tornado 2.2.1

Apr 23, 2012

Security fixes

- `tornado.web.RequestHandler.set_header` now properly sanitizes input values to protect against header injection, response splitting, etc. (it has always attempted to do this, but the check was incorrect). Note that redirects, the most likely source of such bugs, are protected by a separate check in `RequestHandler.redirect`.

Bug fixes

- Colored logging configuration in `tornado.options` is compatible with Python 3.2.3 (and 3.3).

6.9.43 What’s new in Tornado 2.2

Jan 30, 2012

Highlights

- Updated and expanded WebSocket support.
- Improved compatibility in the Twisted/Tornado bridge.
- Template errors now generate better stack traces.
- Better exception handling in `tornado.gen`.

Security fixes

- `tornado.simple_httpclient` now disables SSLv2 in all cases. Previously SSLv2 would be allowed if the Python interpreter was linked against a pre-1.0 version of OpenSSL.

Backwards-incompatible changes

- `tornado.process.fork_processes` now raises `SystemExit` if all child processes exit cleanly rather than returning `None`. The old behavior was surprising and inconsistent with most of the documented examples of this function (which did not check the return value).
- On Python 2.6, `tornado.simple_httpclient` only supports SSLv3. This is because Python 2.6 does not expose a way to support both SSLv3 and TLSv1 without also supporting the insecure SSLv2.
- `tornado.websocket` no longer supports the older “draft 76” version of the websocket protocol by default, although this version can be enabled by overriding `tornado.websocket.WebSocketHandler.allow_draft76`. 
tornado.httpclient

- SimpleAsyncHTTPClient no longer hangs on HEAD requests, responses with no content, or empty POST/PUT response bodies.
- SimpleAsyncHTTPClient now supports 303 and 307 redirect codes.
- tornado.curl_httpclient now accepts non-integer timeouts.
- tornado.curl_httpclient now supports basic authentication with an empty password.

tornado.httpserver

- HTTPServer with xheaders=True will no longer accept X-Real-IP headers that don’t look like valid IP addresses.
- HTTPServer now treats the Connection request header as case-insensitive.

tornado.ioloop and tornado.iostream

- IOStream.write now works correctly when given an empty string.
- IOStream.read_until (and read_until_regex) now perform better when there is a lot of buffered data, which improves performance of SimpleAsyncHTTPClient when downloading files with lots of chunks.
- SSLIOStream now works correctly when ssl_version is set to a value other than SSLv23.
- Idle IOLoops no longer wake up several times a second.
- tornado.ioloop.PeriodicCallback no longer triggers duplicate callbacks when stopped and started repeatedly.

tornado.template

- Exceptions in template code will now show better stack traces that reference lines from the original template file.
- {# and #} can now be used for comments (and unlike the old {% comment %} directive, these can wrap other template directives).
- Template directives may now span multiple lines.

tornado.web

- Now behaves better when given malformed Cookie headers
- RequestHandler.redirect now has a status argument to send status codes other than 301 and 302.
- New method RequestHandler.on_finish may be overridden for post-request processing (as a counterpart to RequestHandler.prepare)
- StaticFileHandler now outputs Content-Length and Etag headers on HEAD requests.
- StaticFileHandler now has overridable get_version and parse_url_path methods for use in subclasses.
- RequestHandler.static_url now takes an include_host parameter (in addition to the old support for the RequestHandler.include_host attribute).
### tornado.websocket

- Updated to support the latest version of the protocol, as finalized in RFC 6455.
- Many bugs were fixed in all supported protocol versions.
- `tornado.websocket` no longer supports the older “draft 76” version of the websocket protocol by default, although this version can be enabled by overriding `tornado.websocket.WebSocketHandler.allow_draft76`.
- `WebSocketHandler.write_message` now accepts a `binary` argument to send binary messages.
- Subprotocols (i.e. the `Sec-WebSocket-Protocol` header) are now supported; see the `WebSocketHandler.select_subprotocol` method for details.
- `WebSocketHandler.get_websocket_scheme` can be used to select the appropriate url scheme (`ws://` or `wss://`) in cases where `HTTPRequest.protocol` is not set correctly.

### Other modules

- `tornado.auth.TwitterMixin.authenticate_redirect` now takes a `callback_uri` parameter.
- `tornado.auth.TwitterMixin.twitter_request` now accepts both URLs and partial paths (complete URLs are useful for the search API which follows different patterns).
- Exception handling in `tornado.gen` has been improved. It is now possible to catch exceptions thrown by a `Task`.
- `tornado.netutil.bind_sockets` now works when `getaddrinfo` returns duplicate addresses.
- `tornado.platform.twisted` compatibility has been significantly improved. Twisted version 11.1.0 is now supported in addition to 11.0.0.
- `tornado.process.fork_processes` correctly reseeds the `random` module even when `os.urandom` is not implemented.
- `tornado.testing.main` supports a new flag `--exception_on_interrupt`, which can be set to false to make Ctrl-C kill the process more reliably (at the expense of stack traces when it does so).
- `tornado.version_info` is now a four-tuple so official releases can be distinguished from development branches.

### 6.9.44 What’s new in Tornado 2.1.1

#### Oct 4, 2011

### Bug fixes

- Fixed handling of closed connections with the `epoll` (i.e. Linux) `IOLoop`. Previously, closed connections could be shut down too early, which most often manifested as “Stream is closed” exceptions in `SimpleAsyncHTTPClient`.
- Fixed a case in which chunked responses could be closed prematurely, leading to truncated output.
- `IOStream.connect` now reports errors more consistently via logging and the close callback (this affects e.g. connections to localhost on FreeBSD).
- `IOStream.read_bytes` again accepts both `int` and `long` arguments.
• **PeriodicCallback** no longer runs repeatedly when **IOLoop** iterations complete faster than the resolution of **time.time()** (mainly a problem on Windows).

**Backwards-compatibility note**

• Listening for **IOLoop.ERROR** alone is no longer sufficient for detecting closed connections on an otherwise unused socket. **IOLoop.ERROR** must always be used in combination with **READ** or **WRITE**.

### 6.9.45 What’s new in Tornado 2.1

**Sep 20, 2011**

**Backwards-incompatible changes**

• Support for secure cookies written by pre-1.0 releases of Tornado has been removed. The **RequestHandler.get_secure_cookie** method no longer takes an **include_name** parameter.

• The **debug** application setting now causes stack traces to be displayed in the browser on uncaught exceptions. Since this may leak sensitive information, debug mode is not recommended for public-facing servers.

**Security fixes**

• Diginotar has been removed from the default CA certificates file used by **SimpleAsyncHTTPClient**.

**New modules**

• **tornado.gen**: A generator-based interface to simplify writing asynchronous functions.

• **tornado.netutil**: Parts of **tornado.httpserver** have been extracted into a new module for use with non-HTTP protocols.

• **tornado.platform.twisted**: A bridge between the Tornado IOLoop and the Twisted Reactor, allowing code written for Twisted to be run on Tornado.

• **tornado.process**: Multi-process mode has been improved, and can now restart crashed child processes. A new entry point has been added at **tornado.process.fork_processes**, although **tornado.httpserver.HTTPServer.start** is still supported.

**tornado.web**

• **tornado.web.RequestHandler.write_error** replaces **get_error_html** as the preferred way to generate custom error pages (**get_error_html** is still supported, but deprecated)

• In **tornado.web.Application**, handlers may be specified by (fully-qualified) name instead of importing and passing the class object itself.

• It is now possible to use a custom subclass of **StaticFileHandler** with the **static_handler_class** application setting, and this subclass can override the behavior of the **static_url** method.

• **StaticFileHandler** subclasses can now override **get_cache_time** to customize cache control behavior.

• **tornado.web.RequestHandler.get_secure_cookie** now has a **max_age_days** parameter to allow applications to override the default one-month expiration.
set_cookie now accepts a max_age keyword argument to set the max-age cookie attribute (note underscore vs dash).

tornado.web.RequestHandler.set_default_headers may be overridden to set headers in a way that does not get reset during error handling.

RequestHandler.add_header can now be used to set a header that can appear multiple times in the response.

RequestHandler.flush can now take a callback for flow control.

The application/json content type can now be gzipped.

The cookie-signing functions are now accessible as static functions tornado.web.create_signed_value and tornado.web.decode_signed_value.

tornado.httpserver

To facilitate some advanced multi-process scenarios, HTTPServer has a new method add_sockets, and socket-opening code is available separately as tornado.netutil.bind_sockets.

The cookies property is now available on tornado.httpserver.HTTPRequest (it is also available in its old location as a property of RequestHandler).

tornado.httpserver.HTTPServer.bind now takes a backlog argument with the same meaning as socket.listen.

HTTPServer can now be run on a unix socket as well as TCP.

Fixed exception at startup when socket.AI_ADDRCONFIG is not available, as on Windows XP.

IOLoop and IOStream

IOStream performance has been improved, especially for small synchronous requests.

New methods tornado.iostream.IOStream.read_until_close and tornado.iostream.IOStream.read_until_regex.

IOStream.read_bytes and IOStream.read_until_close now take a streaming_callback argument to return data as it is received rather than all at once.

IODloop.add_timeout now accepts datetime.timedelta objects in addition to absolute timestamps.

PeriodicCallback now sticks to the specified period instead of creeping later due to accumulated errors.

tornado.ioloop.IOLoop and tornado.httpclient.HTTPClient now have close() methods that should be used in applications that create and destroy many of these objects.

IODloop.install can now be used to use a custom subclass of IOLoop as the singleton without monkey-patching.

IOStream should now always call the close callback instead of the connect callback on a connection error.

The IOStream close callback will no longer be called while there are pending read callbacks that can be satisfied with buffered data.
tornado.simple_httpclient

- Now supports client SSL certificates with the `client_key` and `client_cert` parameters to `tornado.httpclient.HTTPRequest`
- Now takes a maximum buffer size, to allow reading files larger than 100MB
- Now works with HTTP 1.0 servers that don't send a Content-Length header
- The `allow_nonstandard_methods` flag on HTTP client requests now permits methods other than POST and PUT to contain bodies.
- Fixed file descriptor leaks and multiple callback invocations in `SimpleAsyncHTTPClient`
- No longer consumes extra connection resources when following redirects.
- Now works with buggy web servers that separate headers with \n instead of \r\n\r\n.
- Now sets `response.request_time` correctly.
- Connect timeouts now work correctly.

Other modules

- `tornado.auth.OpenIdMixin` now uses the correct realm when the callback URI is on a different domain.
- `tornado.autoreload` has a new command-line interface which can be used to wrap any script. This replaces the `--autoreload` argument to `tornado.testing.main` and is more robust against syntax errors.
- `tornado.autoreload.watch` can be used to watch files other than the sources of imported modules.
- `tornado.database.Connection` has new variants of `execute` and `executemany` that return the number of rows affected instead of the last inserted row id.
- `tornado.locale.load_translations` now accepts any properly-formatted locale name, not just those in the predefined `LOCALE_NAMES` list.
- `tornado.options.define` now takes a `group` parameter to group options in `--help` output.
- Template loaders now take a `namespace` constructor argument to add entries to the template namespace.
- `tornado.websocket` now supports the latest (“hybi-10”) version of the protocol (the old version, “hixie-76” is still supported; the correct version is detected automatically).
- `tornado.websocket` now works on Python 3

Bug fixes

- Windows support has been improved. Windows is still not an officially supported platform, but the test suite now passes and `tornado.autoreload` works.
- Uploading files whose names contain special characters will now work.
- Cookie values containing special characters are now properly quoted and unquoted.
- Multi-line headers are now supported.
- Repeated Content-Length headers (which may be added by certain proxies) are now supported in `HTTPServer`.
- Unicode string literals now work in template expressions.
- The template `{% module %}` directive now works even if applications use a template variable named `modules`.

6.9. Release notes
• Requests with “Expect: 100-continue” now work on python 3

6.9.46 What’s new in Tornado 2.0

Jun 21, 2011

Major changes:
* Template output is automatically escaped by default; see backwards compatibility note below.
* The default AsyncHTTPClient implementation is now simple_httpclient.
* Python 3.2 is now supported.

Backwards compatibility:
* Template autoescaping is enabled by default. Applications upgrading from a previous release of Tornado must either disable autoescaping or adapt their templates to work with it. For most applications, the simplest way to do this is to pass autoescape=\texttt{None} to the Application constructor. Note that this affects certain built-in methods, e.g. \texttt{xsrfs\_form\_html} and \texttt{linkify}, which must now be called with \{\% raw \%\} instead of {}.
* Applications that wish to continue using curl\_httpclient instead of simple\_httpclient may do so by calling
  
  \texttt{AsyncHTTPClient\_configure("tornado.curl\_httpclient.CurlAsyncHTTPClient")}

  at the beginning of the process. Users of Python 2.5 will probably want to use curl\_httpclient as simple\_httpclient only supports ssl on Python 2.6+.
* Python 3 compatibility involved many changes throughout the codebase, so users are encouraged to test their applications more thoroughly than usual when upgrading to this release.

Other changes in this release:
* Templates support several new directives:
  - \{\% autoescape ...\%\} to control escaping behavior
  - \{\% raw ... \%\} for unescaped output
  - \{\% module ... \%\} for calling UIModules
* \{\% module Template(path, **kwargs) \%\} may now be used to call another template with an independent namespace
* All IOSTream callbacks are now run directly on the IOLoop via add\_callback.
* HTTPServer now supports IPv6 where available. To disable, pass family=socket.AF_INET to HTTPServer\_bind().
* HTTPClient now supports IPv6, configurable via allow\_ipv6=bool on the HTTPRequest. allow\_ipv6 defaults to false on simple\_httpclient and true on curl\_httpclient.
* RequestHandlers can use an encoding other than utf-8 for query parameters by overriding decode\_argument().
* Performance improvements, especially for applications that use a lot of IOLoop timeouts
* HTTP OPTIONS method no longer requires an XSRF token.
* JSON output (RequestHandler\_write(dict)) now sets Content-Type to application/json
* Etag computation can now be customized or disabled by overriding RequestHandler\_compute\_etag
* USE\_SIMPLE\_HTTPCLIENT environment variable is no longer supported. Use AsyncHTTPClient\_configure instead.
6.9.47 What’s new in Tornado 1.2.1

Mar 3, 2011

We are pleased to announce the release of Tornado 1.2.1, available from https://github.com/downloads/facebook/tornado/tornado-1.2.1.tar.gz

This release contains only two small changes relative to version 1.2:
* FacebookGraphMixin has been updated to work with a recent change to the Facebook API.
* Running "setup.py install" will no longer attempt to automatically install pycurl. This wasn't working well on platforms where the best way to install pycurl is via something like apt-get instead of easy_install.

This is an important upgrade if you are using FacebookGraphMixin, but otherwise it can be safely ignored.

6.9.48 What’s new in Tornado 1.2

Feb 20, 2011

We are pleased to announce the release of Tornado 1.2, available from https://github.com/downloads/facebook/tornado/tornado-1.2.tar.gz

Backwards compatibility notes:
* This release includes the backwards-incompatible security change from version 1.1.1. Users upgrading from 1.1 or earlier should read the release notes from that release:
  http://groups.google.com/group/python-tornado/browse_thread/thread/b36191c781580cde
* StackContexts that do something other than catch exceptions may need to be modified to be reentrant.
  https://github.com/tornadoweb/tornado/commit/7a7e24143e77481d140fb5579bc67e4c45cbcfad
* When XSRF tokens are used, the token must also be present on PUT and DELETE requests (anything but GET and HEAD)

New features:
* A new HTTP client implementation is available in the module tornado.simple_httpclient. This HTTP client does not depend on pycurl. It has not yet been tested extensively in production, but is intended to eventually replace the pycurl-based HTTP client in a future release of Tornado. To transparently replace tornado.httpclient.AsyncHTTPClient with this new implementation, you can set the environment variable USE_SIMPLE_HTTPCLIENT=1 (note that the next release of Tornado will likely include a different way to select HTTP client implementations)
* Request logging is now done by the Application rather than the RequestHandler. Logging behavior may be customized by either overriding Application.log_request in a subclass or by passing log_function as an Application setting
* Application.listen(port): Convenience method as an alternative to explicitly creating an HTTPServer
* tornado.escape.linkify(): Wrap urls in <a> tags

(continues on next page)
* `RequestHandler.create_signed_value()`: Create signatures like the secure_cookie methods without setting cookies.
* `tornado.testing.get_unused_port()`: Returns a port selected in the same way as `inAsyncHTTPTestCase`.
* `AsynCHTTPTecase.fetch()`: Convenience method for synchronous fetches.
* `IOLoop.set_blocking_signal_threshold()`: Set a callback to be run when the IOLoop is blocked.
* `IOLsream.connect()`: Asynchronously connect a client socket.
* `AsynCHTTPTecase.handle_callback_exception()`: May be overridden in subclass for custom error handling.

HttpRequest has two new keyword arguments, `validate_cert` and `ca_certs`. Setting `validate_cert=False` will disable all certificate checks when fetching https urls. `ca_certs` may be set to a filename containing trusted certificate authorities (defaults will be used if this is unspecified).

* `HTTPRequest.get_ssl_certificate()`: Returns the client's SSL certificate (if client certificates were requested in the server's ssl_options).
* `StaticFileHandler` can be configured to return a default file (e.g. `index.html`) when a directory is requested.
* Template directives of the form "{% from x import y %}" are now supported (in addition to the existing support for "{% import x %}").
* `FacebookGraphMixin.get_authenticated_user` now accepts a new parameter `'extra_fields'` which may be used to request additional information about the user.

**Bug fixes:**
* `auth`: Fixed KeyError with Facebook offline_access.
* `auth`: Uses `request.uri` instead of `request.path` as the default redirect so that parameters are preserved.
* `escape`: `xhtml_escape()` now returns a unicode string, not utf8-encoded bytes.
* `ioloop`: Callbacks added with `add_callback` are now run in the order they were added.
* `ioloop`: `PeriodicCallback.stop` can now be called from inside the callback.
* `iostream`: Fixed several bugs in `SSLIOStream`.
* `iostream`: Detect when the other side has closed the connection even with the select()-based IOLoop.
* `iostream`: `read_bytes(0)` now works as expected.
* `iostream`: Fixed bug when writing large amounts of data on windows.
* `iostream`: Fixed infinite loop that could occur with unhandled exceptions.
* `httpclient`: Fix bugs when some requests use proxies and others don't.
* `httpserver`: `HTTPRequest.protocol` is now set correctly when using the built-in SSL support.
* `httpserver`: When using multiple processes, the standard library's random number generator is re-seeded in each child process.
* `httpserver`: With xheaders enabled, X-Forwarded-Proto is supported as an alternative to X-Scheme.
* `httpserver`: Fixed bugs in multipart/form-data parsing.
* `locale`: `format_date()` now behaves sanely with dates in the future.
* `locale`: Updates to the language list.
* `stack_context`: Fixed bug with contexts leaking through reused IOStreams.
* stack_context: Simplified semantics and improved performance
* web: The order of css_files from UIModules is now preserved
* web: Fixed error with default_host redirect
* web: StaticFileHandler works when os.path.sep != '/' (i.e. on Windows)
* web: Fixed a caching-related bug in StaticFileHandler when a file's
  timestamp has changed but its contents have not.
* web: Fixed bugs with HEAD requests and e.g. Etag headers
* web: Fix bugs when different handlers have different static_paths
* web: @removeslash will no longer cause a redirect loop when applied to the
  root path
* websocket: Now works over SSL
* websocket: Improved compatibility with proxies

Many thanks to everyone who contributed patches, bug reports, and feedback
that went into this release!

-Ben

6.9.49 What's new in Tornado 1.1.1

Feb 8, 2011

Tornado 1.1.1 is a BACKWARDS-INCOMPATIBLE security update that fixes an
XSRF vulnerability. It is available at
https://github.com/downloads/facebook/tornado/tornado-1.1.1.tar.gz

This is a backwards-incompatible change. Applications that previously
relied on a blanket exception for XMLHTTPRequest may need to be modified
to explicitly include the XSRF token when making ajax requests.

The tornado chat demo application demonstrates one way of adding this
token (specifically the function postJSON in demos/chat/static/chat.js).

More information about this change and its justification can be found at

6.9.50 What's new in Tornado 1.1

Sep 7, 2010

We are pleased to announce the release of Tornado 1.1, available from
https://github.com/downloads/facebook/tornado/tornado-1.1.tar.gz

Changes in this release:
* RequestHandler.async_callback and related functions in other classes
  are no longer needed in most cases (although it's harmless to continue
  using them). Uncaught exceptions will now cause the request to be closed

(continues on next page)
even in a callback. If you're curious how this works, see the new
`tornado.stack_context` module.
* The new `tornado.testing` module contains support for unit testing
  asynchronous IOLoop-based code.
* `AsyncHTTPClient` has been rewritten (the new implementation was
  available as `AsyncHTTPClient2` in Tornado 1.0; both names are
  supported for backwards compatibility).
* The `tornado.auth` module has had a number of updates, including support
  for OAuth 2.0 and the Facebook Graph API, and upgrading Twitter and
  Google support to OAuth 1.0a.
* The `websocket` module is back and supports the latest version (76) of
  the websocket protocol. Note that this module's interface is different
  from the websocket module that appeared in pre-1.0 versions of Tornado.
* New method `RequestHandler.initialize()` can be overridden in subclasses
  to simplify handling arguments from URLSpecs. The sequence of methods
  called during initialization is documented at
  http://tornadoweb.org/documentation#overriding-requesthandler-methods
* `get_argument()` and related methods now work on PUT requests in addition
  to POST.
* The `httpclient` module now supports HTTP proxies.
* When `HTTPServer` is run in SSL mode, the SSL handshake is now non-blocking.
* Many smaller bug fixes and documentation updates

Backwards-compatibility notes:
* While most users of Tornado should not have to deal with the `stack_context`
  module directly, users of worker thread pools and similar constructs may
  need to use `stack_context.wrap` and/or `NullContext` to avoid memory leaks.
* The new `AsyncHTTPClient` still works with `libcurl` version 7.16.x, but it
  performs better when both `libcurl` and `pycurl` are at least version 7.18.2.
* OAuth transactions started under previous versions of the `auth` module
  cannot be completed under the new module. This applies only to the
  initial authorization process; once an authorized token is issued that
  token works with either version.

Many thanks to everyone who contributed patches, bug reports, and feedback
that went into this release!

-Ben

### 6.9.51 What's new in Tornado 1.0.1

**Aug 13, 2010**

This release fixes a bug with `RequestHandler.get_secure_cookie`, which would
in some circumstances allow an attacker to tamper with data stored in the
cookie.
6.9.52 What's new in Tornado 1.0

July 22, 2010

We are pleased to announce the release of Tornado 1.0, available from https://github.com/downloads/facebook/tornado/tornado-1.0.tar.gz. There have been many changes since version 0.2; here are some of the highlights:

New features:
* Improved support for running other WSGI applications in a Tornado server (tested with Django and CherryPy)
* Improved performance on Mac OS X and BSD (kqueue-based IOLoop), and experimental support for win32
* Rewritten AsyncHTTPClient available as tornado.httpclient.AsyncHTTPClient2 (this will become the default in a future release)
* Support for standard .mo files in addition to .csv in the locale module
* Pre-forking support for running multiple Tornado processes at once (see HTTPServer.start())
* SSL and gzip support in HTTPServer
* reverse_url() function refers to urls from the Application config by name from templates and RequestHandlers
* RequestHandler.on_connection_close() callback is called when the client has closed the connection (subject to limitations of the underlying network stack, any proxies, etc)
* Static files can now be served somewhere other than /static/ via the static_url_prefix application setting
* URL regexes can now use named groups ("(?P<name>)") to pass arguments to get()/post() via keyword instead of position
* HTTP header dictionary-like objects now support multiple values for the same header via the get_all() and add() methods.
* Several new options in the httpclient module, including prepare_curl_callback and header_callback
* Improved logging configuration in tornado.options.
* UIModule.html_body() can be used to return html to be inserted at the end of the document body.

Backwards-incompatible changes:
* RequestHandler.get_error_html() now receives the exception object as a keyword argument if the error was caused by an uncaught exception.
* Secure cookies are now more secure, but incompatible with cookies set by Tornado 0.2. To read cookies set by older versions of Tornado, pass include_name=False to RequestHandler.get_secure_cookie()
* Parameters passed to RequestHandler.get/post() by extraction from the path now have %-escapes decoded, for consistency with the processing that was already done with other query parameters.

(continues on next page)
Many thanks to everyone who contributed patches, bug reports, and feedback that went into this release!
